rus analogue of 3,4-dihydrobenzvalene or as a $P_{4}$ tetrahedron open at one edge and bridged by a $\mathrm{P}_{2} \mathrm{R}_{2}$ unit. The considerable stability of 3 toward air may be ascribed to the good steric shielding of the phosphorus framework by the pentamethylcyclopentadienyl ligands.

The syntheses of $\mathbf{2}$ and $\mathbf{3}$ from $\mathbf{1}$ are further examples of the preparative utility of the labile phosphorus-carbon bond in pentamethylcyclopentadieny!-substituted phosphorus compounds. ${ }^{\left[9 \text { c. }{ }^{11]} \text { Clearly, the new cyclophosphanes } 2 \text { and } 3\right.}$ with their functionalized $\mathrm{P}_{6} \mathrm{R}_{\mathrm{x}}$ frameworks have promising synthetic potential. ${ }^{[11 \mathrm{~d}]}$

## Experimental Procedure

2: A solution of $1(3.40 \mathrm{~g}, 6.82 \mathrm{mmol})$ in 35 mL of benzene was refluxed for 20 h . The solvent was then removed under vacuum from the clear, orange reaction solution until the viscous residue (ca. 3.5 g ) began to form bubbles. Shortly after addition of 7 mL of $n$-hexane, the deep orange oil solidified to a yellow crystalline mass. After removal of the supernatant liquid, 2 was recrystallized from $n$-hexane. Yield: $2.05 \mathrm{~g}(66 \%) 2 \cdot n-\mathrm{C}_{6} \mathrm{H}_{14}$; correct elemental analysis. ${ }^{1} \mathrm{H}$ NMR ( $300 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ) : $\delta=0.9-2.2$ (complex multiplet; $\mathrm{C}_{5} \mathrm{Me}_{5}$, $n-\mathrm{C}_{6} \mathrm{H}_{14}$ ). ${ }^{13} \mathrm{C}$ NMR ( $75 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta=11.0-23.0$ (Me), $57.4-59.7$ (P-C), 134.8. 135.5, 136.0, 136.4, 139.7, 141.0, 141.6, $141.7\left(\mathrm{sp}^{2}-\mathrm{C}\right) .{ }^{31} \mathrm{P}$ NMR ( $121 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta=78$ (2P), $60(1 \mathrm{P}),-121(2 \mathrm{P}),-129(1 \mathrm{P}) . \mathrm{MS}(\mathrm{m} / \mathrm{z}$; rel. int.): $\mathrm{P}_{6}\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{3}^{\oplus}(591 ; 18), \mathrm{P}_{6}\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2}^{\oplus}(456 ; 2), \mathrm{P}_{3}\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2}^{\oplus}$ (363; 4), $\mathrm{P}_{6}\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)^{\oplus}(321 ; 34), \mathrm{C}_{5} \mathrm{Me}_{5}^{\oplus}(135 ; 100)$.
$3: 2 \cdot n-\mathrm{C}_{6} \mathrm{H}_{14}(5.50 \mathrm{~g}, 6.77 \mathrm{mmol})$ was refluxed in 70 mL of xylene for 45 min . After removal of the solvent, the orange residue was treated with 20 mL of $n$-hexane. The precipitated pale yellow powder (ca. 2.5 g ) was filtered off and recrystallized several times from $n$-hexane. Yield: 1.42 g ( $46 \%$ ) 3; correct elemental analysis. ${ }^{1} \mathrm{H}$ NMR ( $300 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta=1.3-2.1$, ${ }^{13} \mathrm{C}$ NMR $\left(75 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}\right): \delta=10.9-21.7$ (Me), 57.4 (P-C), 136.8, 137.7, 139.5, 140.2 ( $\mathrm{sp}^{2}-\mathrm{C}$ ). ${ }^{31} \mathrm{P}$ NMR (121 MHz, $\mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta=105,70,-237$ (intensities $1: 1: 1$ ). MS ( $m / z:$ rel. int.): $M^{\oplus}(456 ; 9), \mathrm{P}_{6}\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)^{\oplus}(321 ; 44), \mathrm{C}_{5} \mathrm{Me}_{5}^{\oplus}(135 ; 100)$.

## Photocycloadditions of Benzvalene **

## By Manfred Christl* and Max Braun

In 1975, Katz and Turro et al! ${ }^{[1]}$ reported that the sensitized photolysis of benzvalene 1 can lead to two rearrangements. Transformation to benzene occurs with sensitizers with a triplet energy $E_{\mathrm{T}}>65 \mathrm{kcal} \mathrm{mol}^{-1}$, whereas automerization (1,3-C migration) is induced by those with $E_{T}<$ $63 \mathrm{kcal} \mathrm{mol}^{-1}$. Although the sensitizers used were mainly ketones, which are typical substrates for the Paterno-Büchi reaction, ${ }^{[2]}$ the authors mentioned no products with oxetane structure. In view of the high reactivity of benzvalene toward a wide variety of electrophiles, ${ }^{[3]}$ we wanted to know whether, besides the isomerizations noted above, photochemical cycloadditions of 1 take place.

Irradiation ${ }^{[4]}$ of $1^{[5]}$ in the presence of acetone and benzophenone ( $E_{\mathrm{T}}=78$ and $69 \mathrm{kcal} \mathrm{mol}^{-1}$, respectively ${ }^{[2 \mathrm{a}]}$ ) resulted in the formation of benzene. However, with biacetyl ( $E_{\mathrm{T}}=56 \mathrm{kcal} \mathrm{mol}^{-1[2 \mathrm{a}]}$ ), benzil ( $\left.54 \mathrm{kcal} \mathrm{mol}^{-1[2 \mathrm{a}]}\right)$, methyl phenylglyoxylate $\left(61.9 \mathrm{kcal} \mathrm{mol}^{-1},{ }^{[68]}\right.$ irradiation at $-30^{\circ} \mathrm{C}$ ), 1,4-benzoquinone ( $50 \mathrm{kcal} \mathrm{mol}^{-1[2 \mathrm{a}]}$ ), and chloranil ( $56.4 \mathrm{kcal} \mathrm{mol}^{-1}, 16 \mathrm{bj}$ irradiation at $-30^{\circ} \mathrm{C}$ ), the oxetanes 2 ( $19 \%$ ), 4 ( $22 \%$ ), 5 ( $38 \%$ ), 6 ( $25 \%$ ), and $7(51 \%)$, respectively, were obtained ${ }^{[7]}$ In the experiment with biacetyl, we observed, in addition to 2 , the oxadihydrosemibullvalene $\mathbf{3}$ (2:3 $\approx 30: 1$ ), which is also accessible, together with a small amount of its diastereomer, in $48 \%$ yield by treatment of 2 with $\mathrm{AgBF}_{4}$ in $\mathrm{CDCl}_{3}$ at $20^{\circ} \mathrm{C} \cdot{ }^{[7]}$ The experiment with chloranil afforded pure 7 only at $-30^{\circ} \mathrm{C}$; at $20^{\circ} \mathrm{C}$, besides $\overline{7}$, the rearrangement product $8^{[7]}(7: 8=4: 1)$ was formed. For selected physical data for 2-8, see Table 1.

[^0]The formation of 3 confirms the multistep mechanism of the Paterno-Büchi reaction. ${ }^{[2]}$ Compound 1 and biacetyl in its triplet state presumably give the diradical 9 , which can then either cyclize to $\mathbf{2}$ or undergo a cyclopropylmethyl-homoallyl rearrangement, ${ }^{[3 a]}$ to afford 10 , provided that, of the two $\mathrm{C}-\mathrm{C}$ bonds in question in 9 , the bond cis to the biacetyl moiety breaks. Diradical 10 would then collapse to 3. In agreement with this mechanism, $\left[1,6-\mathrm{D}_{2}\right]$ benzvalene yields the dideuterated products $\left[3,4-\mathrm{D}_{2}\right]-2$ and $\left[2,8-\mathrm{D}_{2}\right]-3$.

The finding that the labels in 2 are limited to positions 3 and $4^{[8]}$ rules out the automerization of 1 by the excited sensitizer biacetyl. We arrived at the same conclusion by recovering unused $\left[D_{2}\right]-1$ and allowing it to react with $2,4,6-$ trimethylbenzonitrile oxide. In the resulting dihydroisoxazole, ${ }^{[9]}$ we found the deuterium atoms also restricted to the bicyclobutane bridgehead positions. ${ }^{[8]}$ Interestingly, Katz and Turro et al. ${ }^{[1]}$ included biacetyl in their table of sensitizers but did not enter a quantum yield for the automerization of 1 . The latter was given as ca. 0.2 for benzil as sensitizer. We have now confirmed that excited benzil effects the automerization of 1 . Adduct $\left[\mathrm{D}_{2}\right]-4$ was obtained from $\left[1,6-\mathrm{D}_{2}\right]-1$ with the ratio of the labels in positions 1 (6), 2 (5), and 3 (4) being $1: 3: 45 .{ }^{[8]}$ Analysis of the $2,4,6$-trimethylbenzonitrile oxide adduct revealed that the labels in unused $\left[\mathrm{D}_{2}\right]-1$ were more evenly distributed, namely in a ratio of 1:2:4 in the positions corresponding to those in $4 .{ }^{[8]}$ Irradiation of 1,4benzoquinone and 2 -benzoylthiophene (see below) in the presence of $\left[1,6-D_{2}\right]-1$ did not lead to a $1,3-C$ migration in $\left[1,6-D_{2}\right]-1$. Whether benzvalene 1 undergoes automerization in the presence of ketones in the triplet state ( $E_{\mathrm{T}}<63 \mathrm{kcal} \mathrm{mol}^{-1}$ ), therefore, is a question of relative reaction rates. With biacetyl, 1,4-benzoquinone, and 2-benzoylthiophene, the cycloaddition occurs appreciably faster than the energy transfer required for automerization of $\mathbf{1}$; the two rates are similar in the case of benzil.
The structure of the product 8 indicates that it is not formed via a diradical analogous to 9 . A radical ion pair is known to be formed upon irradiation of chloranil in the presence of a donor; ${ }^{[10 \mathrm{az}]}$ for 1 as donor, this was shown by CIDNP signals of 1 and benzene. ${ }^{[106]}$ Thus, 8 is presumably formed via the radical ion pair, which collapses to zwitterion

19: oil. IR $\left(\mathrm{CCl}_{4}\right): \tilde{v}=1708 \mathrm{~cm}^{-1}(\mathrm{C}=\mathrm{O})$
11. A Wagner-Meerwein rearrangement in the cationic moiety of 11 involving migration of the bicyclobutane bridgehead carbon atom trans to the anionic moiety ${ }^{[3]}$ would then have to occur to give 12 , which would subsequently yield 8 .

In contrast to the reaction with 1,4-benzoquinone, irradiation ${ }^{[4]}$ of $1^{[5]}$ with 1,4 -naphthoquinone $\left(E_{\mathrm{T}}=57 \mathrm{kcal}\right.$ $\mathrm{mol}^{-1[6 \mathrm{c}]}$ ) at $-30^{\circ} \mathrm{C}$ gave the cyclobutane $13^{[7]}(17 \%)$. Motivated by the work of Cantrell, ${ }^{[113}$ we also employed 2-benzoylthiophene ( $62.6 \mathrm{kcal} \mathrm{mol}^{-1[11]}$ ) at room temperature as well as 2-acetylthiophene ( $64.5 \mathrm{kcal} \mathrm{mol}^{-1[111}$ ) and 2-acetylfuran ( $64.9 \mathrm{kcal} \mathrm{mol}^{-1(11)}$ ) at $-30^{\circ} \mathrm{C}$ and obtained the [2+2] cycloadducts $14(21 \%)$, and $\mathbf{1 5}(27 \%)$ as well as the $[4+2]$ cycloadduct $\mathbf{1 6}(19 \%)$ together with its diastereomer $(6 \%) .{ }^{[7]} \mathrm{At}-30^{\circ} \mathrm{C}$, excited 1-acetylnaphthalene ( 56.4 kcal $\mathrm{mol}^{-1}{ }^{[64]}$ ) and $1^{[5]}$ gave initially the [ $\left.4+2\right]$ cycloadduct 17 ( $25 \%$ ). Upon further irradiation, however, 17 was converted at a similar rate into $18(41 \%)$ and $19(9 \%)^{[7]}$ (di- $\pi$-methane rearrangement). Selected physical data for $13-19$ are given in Table 1.

We obtained no cycloadduct from 1 and cyclopent-2-en-1one ( $E_{\mathrm{r}}=74 \mathrm{kcal} \mathrm{mol}^{-1[2 \mathrm{a}]}$ ). In conclusion, 1, too, can undergo photochemical cycloadditions, provided that the reaction partner has a triplet energy $E_{\mathrm{T}}<65 \mathrm{kcal} \mathrm{mol}^{-1}$.

[7] The isolation was carried out by flash chromatography with petroleum ether/ethyl acetate on $\mathrm{SiO}_{2}(4-8,13-15)$ or on basic $\mathrm{Al}_{2} \mathrm{O}_{3}$, activity III (17-19), and by preparative gas chromatography with Carbowax 20 M on Volaspher * A $2(2,3)$ or silicon SE 30 on Chromosorb* W (16 and diastereomer). Elemental analyses as well as mass, IR, and NMR spectra support the proposed structures. Except for 13, the configurations were determined from the characteristic magnitudes of the coupling constants or from NOE effects.

## Synthesis and Structure of Digerma- and Distannacyclobutenes**

By Adolf Krebs,* Andrea Jacobsen-Bauer, Erhard Haupt, Michael Veith,* and Volker Huch

The first germirenes (germacyclopropenes) were synthesized by reaction of 3,3,6,6-tetramethyl-1-thiacyclohept-4yne 1 with suitable precursors of dialkylgermylenes (dialkylgermanediyls); ${ }^{[1]} 1$ combines high reactivity of the $\mathrm{C}-\mathrm{C}$ triple bond with steric shielding of the resulting addition product, thereby often making possible the synthesis of systems otherwise accessible only with difficulty. ${ }^{[2]}$ Since, until recently, no addition reactions of stannylenes to $\mathrm{C}-\mathrm{C}$ triple bonds had been described, ${ }^{[3]}$ we allowed 1 to react with the stabilized diaminogermylene $2^{[4]}$ as well as the diaminostannylene $3^{[4]}$ and obtained, in addition to the digermacyclobutene 4, the first distannacyclobutene 5. Compounds 4 and 5 are both dispiro compounds.

Addition of $\mathbf{1}$ to the red solution of $\mathbf{3}$ in various solvents (benzene, THF, $n$-hexane, diethyl ether) resulted in immediate precipitation of a yellow solid, whose ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectroscopic data in concentrated solution indicate the formation of the $1: 2$ adduct 5 . In dilute solution, however, only the ${ }^{1} \mathrm{H}$ NMR signals of the starting materials were observed; in the ${ }^{13} \mathrm{C}$ NMR spectrum of 5 , the signal for the sp-hybridized C atom of 1 was absent. Proof for the presence of an $\mathrm{Sn}-\mathrm{Sn}$ bond was provided by the ${ }^{119} \mathrm{Sn}$ NMR spectrum, which showed a signal at $\delta=+155$ (rel. to $\mathrm{Sn}\left(\mathrm{CH}_{3}\right)_{4}$; $J\left({ }^{119} \mathrm{Sn},{ }^{117} \mathrm{Sn}\right)=3723 \mathrm{~Hz}$ ). Compound 4 was synthesized in a similar way from 1 and 2 .

The results of the X-ray structure analyses of $\mathbf{4}$ and $\mathbf{5}$ are given in Figure 1. They confirm the structure derived for 5 in solution. In both cases, there is a central four-membered ring containing two $\mathrm{sp}^{2}$-hybridized carbon atoms and two fourfold coordinated germanium or tin atoms, respectively. Whereas in 5 the nearly planar peripheral diazasilastanna four-membered rings are perpendicular to the completely planar central distannacyclobutene ( 5 has a $C_{2}$ axis in the crystal, the thiacycloheptene unit being disordered; only one of the two variants is shown in Fig. 1), the diazasilagerma four-membered rings in 4 , which are also planar, are twisted
