Promotionskolloquium: _____ in Würzburg

Aushändigung Doktorurkunde: _____ in Würzburg

TABLE OF CONTENTS

ACKNOWLEDGEMENTS

This dissertation was conducted in the laboratory of the Orthopaedic Centre for Musculoskeletal Research, which is integrated in the university Orthopaedic Clinic of Würzburg, Bavaria. My research project would not have been possible without the support of many people. Therefore, it is a pleasure to thank all supervisors and colleagues of the research centre for their support in a number of ways.

I am very grateful to my direct supervisor, Prof. Dr. Norbert Schütze, whose encouragement, supervision and support from the preliminary to the concluding level enabled me to develop an understanding and arbitrary handling of the subject. Furthermore, I am very thankful for the opportunities to present important parts of my work at national and international symposia.

I would also thank Prof. Dr. Georg Krohne of the Faculty of Biology (University of Würzburg) for accepting the position of an assessor, thereby enabling this scientific dissertation at the Faculty of Medicine.

I am indebted to many of my colleagues, but especially to Roderich Laug, Viola Zehe and Patrick Prager, for their invaluable assistance with my laboratory tasks and mental support during the last years.

Further I would like to thank the entire working groups of Prof. Dr. Franz Jakob, PD Dr. André Steinert and PD Dr. Ulrich Nöth for their helpfulness and cooperation in many aspects and Monika Hofmann for her patient help with any kind of organizational tasks in the Orthopaedic Clinic.

I also deeply acknowledge the support of my parents. They always assisted me financially and particularly morally during my education and finally the conduction of this thesis. In this context, I also would like to thank my brother Timm. Once, his trust in my abilities encouraged me to keep on finding my own ways. I am very glad that he was right after all. ;)

Lastly, I owe my deepest gratitude to my boyfriend Alex, for his support in performing microarray analyses, for sharing his statistical skills, for reviewing my thesis consistently, for his patient and moderate way to answer all my questions and at least for his comprehension and encouragement during all stages of this dissertation. Thank you so much!

SUMMARY/ZUSAMMENFASSUNG

Summary

Human adult cartilage is an aneural and avascular type of connective tissue, which consequently reflects reduced growth and repair rates. The main cell type of cartilage are chondrocytes, previously derived from human mesenchymal stem cells (hMSCs). They are responsible for the production and maintainance of the cartilaginous extracellular matrix (ECM), which consists mainly of collagen and proteoglycans. Signal transmission to or from chondrocytes, generally occurs via interaction with signalling factors connected to the cartilaginous ECM. In this context, proteins of the CCN family were identified as important matricellular and multifunctional regulators with high significance during skeletal development and fracture repair. In this thesis, main focus lies on WISP1/CCN4, which is known as a general survival factor in a variety of cell types and seems to be crucial during lineage progression of hMSCs into chondrocytes. We intend to counter the lack of knowledge about the general importance of WISP1-signalling within the musculoskeletal system and especially regarding cell death and survival by a variety of molecular and cell biology methods.

First, we established a successful down-regulation of endogenous WISP1 transcripts within different cell types of the human musculoskeletal system through gene-silencing. Interestingly, WISP1 seems to be crucial to the survival of all examined cell lines and primary hMSCs, since a loss of WISP1 resulted in cell death. Bioinformatical analyses of subsequent performed microarrays (WISP1 down-regulated vs. control samples) confirmed this observation in primary hMSCs and the chondrocyte cell line Tc28a2. Distinct clusters of regulated genes, closely related to apoptosis induction, could be identified. In this context, TRAIL induced apoptosis as well as p53 mediated cell death seem to play a crucial role during the absence of WISP1 in hMSCs. By contrast, microarray analysis of WISP1 down-regulated chondrocytes indicated rather apoptosis induction via MAPK-signalling. Despite apoptosis relevant gene regulations, microarray analyses also identified clusters of differentially expressed genes of other important cellular activities, e.g. a huge cluster of interferon-inducible genes in hMSCs or gene regulations affecting cartilage homeostasis in chondrocytes.

Results of this thesis emphasize the importance of regulatory mechanisms that influence cell survival of primary hMSCs and chondrocytes in the enforced absence of WISP1. Moreover, findings intensified the assumed importance for WISP1-signalling in cartilage homeostasis. Thus, this thesis generated an essential fundament for further examinations to investigate the role of WISP1-signalling in cartilage homeostasis and cell death.

Zusammenfassung

Humaner adulter Knorpel besitzt weder Blutgefäße noch Nerven, weswegen diese Knorpelart im Vergleich zu anderen Gewebetypen ein verringertes Wachstum und Regenerierung wiederspiegelt. Den Hauptteil der Zellen im adulten Knorpel stellen die Chondrozyten (Knorpelzellen) dar, welche sich zuvor aus humanen mesenchymalen Stammzellen (hMSCs) entwickelt haben. Sie sind verantwortlich für die Bildung und Aufrechterhaltung der extrazellulären Matrix (ECM) des Knorpelgewebes, welche hauptsächlich aus Kollagen und Proteoglykanen besteht. Signale, die durch Chondrozyten erzeugt oder weitergeleitet werden, finden in der Regel durch Interaktion mit Molekülen der im Knorpel liegenden ECM statt. Mitglieder der CCN-Familie gelten hierbei als bedeutende extrazelluläre Matrixproteine, die bei verschiedenen regulatorischen Prozessen während der Skelettentwicklung und der Frakturheilung eine Rolle spielen. In dieser Doktorarbeit liegt das Hauptaugenmerk auf dem CCN Protein WISP1/CCN4. Dieses Protein gilt bereits in verschiedenen Zellen als ein notwendiger Überlebensfaktor und scheint des Weiteren eine regulatorische Funktion während der Differenzierung von hMSCs in Chondrozyten auszuüben. Die generelle Bedeutung von WISP1 für das muskuloskelettale System ist bislang jedoch weitgehend ungeklärt und soll während dieser Doktorarbeit mittels einer Reihe von molekular- und zellbiologischer Methoden genauer untersucht werden.

Hierfür wurde zu Beginn eine erfolgreiche Herunterregulierung endogen hergestellter WISP1 Transkripte mittels Genexpressionshemmung (gene-silencing) in verschiedenen muskuloskelettalen Zellen erzielt. Interessanterweise scheint WISP1 eine bedeutende Rolle für das Überleben dieser Zellen zu spielen, da ein Verlust bei allen untersuchten Zelllinien und primären hMSCs zum Zelltod führte. Um zu Grunde liegende Mechanismen genauer zu untersuchen, wurden daraufhin Microarray Analysen von hMSCs und Tc28a2 Chondrocyten durchgeführt (jeweils WISP1 herunterreguliert vs Kontrollzellen). In diesem Zusammenhang identifizierten bioinformatische Analysen differentielle Expressionen verschiedener apoptoseresponsiver Gene. So scheint eine Apoptoseinduktion über TRAIL und/oder p53 in hMSCs stattzufinden, wohingegen eine starke Regulation des MAPK-Signalweges in Chondrozyten detektiert wurde. Neben diesen Genregulationen, deckten die Analysen ebenso Gengruppen auf, die bei anderen wichtigen zellulären Abläufen eine Rolle spielen. Hier sind in WISP1 herunterregulierten hMSCs u.a. viele differenziell exprimierte Gene zu nennen, die durch Interferone induzierbar sind. In Chondrozyten dagegen scheint eine verringerte WISP1 Expression Genexpressionen zu beeinflussen, welche die Knorpelhomeostase regulieren.

Die Ergebnisse, die während dieser Doktorarbeit erzielt wurden, verdeutlichen die Wichtigkeit von WISP1 für das Überleben von primären hMSCs und Chondrozyten. Darüberhinaus verstärken die bioinformatischen Analysen die Annahme, das WISP1 regulatorische Funktionen für die Knorpelhomeostase ausübt. Somit bietet diese Doktorarbeit ein essentielles Fundament, um die Rolle von WISP1 bei der Aufrechterhaltung der Knorpelhomeostase und des Zelltodes weiter zu erforschen.

Part I.

Introduction

CHAPTER

ONE

MUSCULOSKELETAL SYSTEM

The human musculoskeletal system comprises over 200 bones as well as cartilage, muscles, ligaments and all associated connective tissues. Main functions of the musculoskeletal system are to stabilize the whole body, protecting organs and facilitate movements. Beside these well known features, it additionally plays important roles in a variety of metabolic and regulatory processes. Bones, for example, serve as a main storage for minerals, thereby controling organs and cellular activities (Martin 1983). Further, bones and their adhesive musculoskeletal tissues regulate important physiological processes through keeping a general stem cell reservoir and initiating development or differentiation of blood cells. Regarding all of these functions together, the musculoskeletal system represents an essential part of the human body, which has often been under-estimated and neglected in fundamental molecular research.

1.1. Cells of the musculoskeletal system

1.1.1. Cells with multilineage differentiation potential: stem cells

The internal cavities of many bones are filled with red marrow containing undifferentiated heamatopoietic stem cells (HSCs) and mesenchymal stem cells (MSCs). Stem cells in general have the capability of replacing or renewing itself to conserve the stem cell pool or developing into specialized cells of a variety of cell types. Thereby, they form new organs during embryonic development or regenerate tissues in adult organisms (Caplan 1991). While totipotent embryonic stem cells can differentiate into all cell types of the organism, multipotent HSCs and MSCs of the adult organism are restricted in their differentiation potential. HSCs are necessary for the constant renewal of blood, thereby producing different types of red blood cells and lymphocytes (Baum et al. 1992; Reya 2003; Till and McCulloch 2011). MSCs in contrast, generate a limited number of cells of mesenchymal tissues like bone (osteoblasts), cartilage (chondrocytes), muscle (myoblasts), and adipose (adipocytes) (Barry and Murphy 2004; Muraglia et al. 2000; Pereira et al. 1995; Pittenger et al. 1999; Prockop 1997; Verfaillie 2002). MSCs are known as quiescent cells, remaining in the stem cell niche until growth factors initiate asymmetric cell division. This results in one identical daughter cell and one cell with a lineage-dependent specific differentiation program (Baksh et al. 2004; Fuchs et al. 2004). In vitro, it is difficult to differ between pure MSC populations and those containing mixtures of lineage-specific progenitor cells. This is because a single cell marker is not completely proven until now. MSCs, as well as HSCs, are positive for the CD34 antigen directly after the isolation from bone marrow. In contrast to the HSCs, which express CD34 permanently, MSCs loose this antigen during *in vitro* culture (Tuan et al. 2003). Immuno-selection via detection of a

variety of MSC surface markers e.g. STRO-1, src homology 2 (SH2), src homology 3 (SH3), CD44, CD90 and CD146 (Bianco et al. 2001; Gronthos and Simmons 1996; Pittenger et al. 1999; Sacchetti et al. 2007; Simmons et al. 1994) are discussed. They are mostly used together with detection of MSC ability to differentiate in osteocytes, chondrocytes and adipocytes (Nöth et al. 2002; Pittenger et al. 1999; Schilling et al. 2008; Schuetze et al. 2005). The differentiation capacity of MSCs *in vivo* and *in vitro* arouse the interest of many researchers in the area of tissue engineering as well as gene therapy application. This is mainly due to the fact that autologous MSCs induce no immuno-reactivity after transplantation and ethical constraints are not to be expected (Baksh et al. 2004; Bianco and Robey 2001; Young et al. 2005).

1.1.2. Bone remodelling: osteoclasts, osteoblasts and osteocytes

At childbirth, the human body is build up with over 270 bones. During ontogenesis, many bones fuse together leaving a total of 206 separate bones in an adult. But even afterwards, the skeleton is a metabolically active organ that undergoes continuous remodelling throughout life. This involves a balance of removing mature bone tissue - a process called bone resorption - and the replacement with new bone matrix, namely ossification or bone formation (Caplan 2005; Martin 1983). Bone resorption is primary accomplished by multinucleated osteoclasts, which derive from monocytes of the heamatopoietic lineage (Suda et al. 1999; Väänänen et al. 2000). Several cytokines, e.g. interleukin 1 (IL1), nuclear factor kappa B (NFκB), receptor activator of nuclear factor kappa B ligand (RANKL), tumour necrosis factor alpha (TNFα) and hormones e.g. parathyroid hormone (PTH), estrogen and leptin, are essential for osteoclast differentiation, activation and recruitment (Nakamura et al. 2011). After being recruited to a specific site, they attach to the bone surface and seal it off from the extracellular environment. Proteolytic enzymes are secreted to remove the bone matrix and expose the bone mineral (Horowitz et al. 2001).

Osteoblasts, in contrast, are cells that are primarily responsible for ossification. They derive from MSC generated osteoprogenitor cells and function by secreting the bone extracellular matrix (osteoid). Insulin-like growth factor 1 (IGF1), fibroblast growth factor 2 (FGF2), transforming growth factor beta 1 (TGFβ1) and different members of the bone morphing protein (BMP) family are released during bone resorption and seem to be essential for the recruitment of MSCs and subsequent osteogenesis (Habisch et al. 2008; Pederson et al. 2008; Ponte et al. 2007; Sims and Gooi 2008). Mature osteoblasts migrate to previously resorbed sites. They are found in clusters along the bone surface on a layer of bone matrix that they are continuously producing. The osteoid consists mainly of collagen type I fibers, which serves as a scaffold for subsequent calcification. After osteoid secreting, 15% of mature osteoblasts are entrapped in the new bone matrix and differentiate into osteocytes. They can be easily identified by their star-shaped appearance, forming a network of thin canaliculi permeating the entire bone matrix (Hadjidakis and Androulakis 2006). Osteocytes can regulate bone formation by secerning sclerostin, which migrates along the canaliculi to the bone surface. Sclerostin inhibits WNT- and BMP-signalling, therefore decreasing osteoprogenitor cell proliferation and bone mineralization (Galli et al. 2010; ten Dijke et al. 2008).

1.1.3. Cartilage: chondroblasts and chondrocytes

Cartilage is a type of elasticity connective tissue, which is not as tight as bone and less flexible than muscles. The main cell types of cartilage are chondrocytes, previously derived from MSC generated chondroblasts. These cells are responsible for the production and maintenance of the cartilagous extracellular matrix (ECM), a matrix composed of collagen type II fibers, elastin and proteoglycans (Buckwalter and Mankin 1998; Palfrey and Davies 1966). The en-

doskeleton of early vertebrates comprised exclusively a composition of cartilaginous tissues. During vertebrate evolution, cartilage seems to have been gradually replaced by bone formation (Kubota and Takigawa 2011). Thus, the authors of the aforementioned studies classified cartilage roughly into two distinct classes: temporary and permanent cartilages. Temporary cartilage is localized in the cartilage growth plate, where endochondral bone formation took place during the skeletal development (Fukunaga et al. 2003). This process is initiated by MSC condensation and subsequent differentiation into chondrocytes (Hill et al. 2005). Chondrocyte proliferation and hypertrophic differentiation generate a calcified cartilage matrix (Shu et al. 2011). Afterwards, hypertrophic chondrocytes undergo apoptosis, leaving cavities within the bone. Osteoblasts differentiate nearby these cavities, using the calcified cartilage as scaffolds. They deposit bone matrix onto the degraded mineralized cartilaginous matrix, thereby generating the basis for new bones (Hojo et al. 2010).

In contrast to temporary cartilage, permanent cartilage is aneural and avascular and can be found in many areas of the human body. Its function is in most cases dependent on its location. Based upon the relative contribution and distribution of fibers within the ECM, permanent cartilage can be divided into three subgroups: hyaline, elastic and fibrous cartilage. Articular cartilage, the main type of hyaline cartilage, covers the end of bones in joints e.g. knee, elbow, and rib cage. This enables bones to slide smoothly and easily past each other. Interestingly, articular cartilage and the cartilage growth plate develop from the same origin, but chondrocytes in articular cartilage do not undergo hypertrophic differentiation to generate a calcified cartilage matrix. Elastic cartilage, generally found in areas of the human face, is histologically similar to hyaline cartilage, but contains fibers of elastin, which confers more elastic flexibility. Fibrocartilage, found in the meniscus, has the greatest tensile strength and is the only cartilage type that contains collagen type I additional to collagen type II, building a dense matrix by compact collagenous bundles.

In the research area comprising tissue engineering and regenerative medicine, investigation of adult cartilage is of main interest. Since it contains no blood vessels or nerves, it is consequently a connective tissue with reduced growth and repair rates compared to other tissues. Signal transmission to or from chondrocytes generally occurs via interaction with signalling factors of the cartilaginous ECM (Chen and Lau 2010). Thus, top priority of this study was the investigation of potential proteins that modify signalling of molecules associated with the ECM.

CHAPTER

TWO

CCN PROTEIN FAMILY

2.1. Nomenclature and development

The CCN family of proteins comprises six distinct members: cysteine-rich 61 (CYR61/CCN1), connective tissue growth factor (CTGF/CCN2), nephroblastoma overexpressed (NOV/CCN3) and WNT-induced secreted proteins-1 (WISP1/CCN4), -2 (WISP2/CCN5) and further -3 (WISP3/CCN6). Each protein is additional numbered by its order of discovery, CCN1-CCN6 (Brigstock 2003) at which the acronym CCN comes from the first three discovered members CYR61, CTGF and NOV (Bradham et al. 1991; Joliot et al. 1992; O'Brien et al. 1990). All members are characterized as matricellular proteins which share up to four structural domains with partial sequence identity to insulin-like growth factor binding proteins (IGFBP domain), von Willebrand factor type C repeat (VWC domain), thrombospondin type 1 repeat (TSP domain) and a C-terminus (CT domain), containing a putative cysteine knot (Fig. 2.1) (Bork 1993; Lau and Lam 1999; Perbal 2001). In addition to the 30-50% amino acid sequence identity, all members contain highly conserved cysteine residues (nearly 10% by mass) spread over the existing domains (Lau and Lam 1999).

Apart from the full-length CCN proteins (including WISP2), also truncated variants, lacking one or more of the four structural domains, have been identified (Perbal 2004). It is well known, that post-translational processing as well as alternative splicing of the corresponding mRNA are the basis of truncated CCN variants. One truncated isoform of WISP1/CCN4 (transcript variant 2; -T2), which lacks the VWC domain has been detected in non-transformed chondrocytes (Yanagita et al. 2007). But mostly, truncated proteins, or proteins missing internal modules, have been shown to be associated with pathological situations (Yanagita et al. 2007).

2.1.1. Multifunctional signalling

In general, CCN proteins are matricellular proteins that modify signalling of molecules associated with the ECM. Induction of expression occurs early in development to facilitate multiple tissue and organ functions. Like many ECM proteins, members of the CCN family comprise multifunctional roles in crucial areas of physiology such as angiogenesis, skeletal development, tumourgenesis, cell proliferation, wound healing, fracture repair and cell survival (Babic et al. 1998; Holloway et al. 2005; Lin et al. 2003, 2005; Nakanishi et al. 2000; Nishida et al. 2000; Schuetze et al. 2005; Zhang et al. 2005). Their functions are on the one hand overlapping, however on the other hand of distinct manner and cell- and tissue-specific (Leask and Abraham 2006; Perbal 2004). Looking at the structural similarities amongst the CCN proteins, it is not easily to understand how functional differences could exist. They comprise a homeostatic

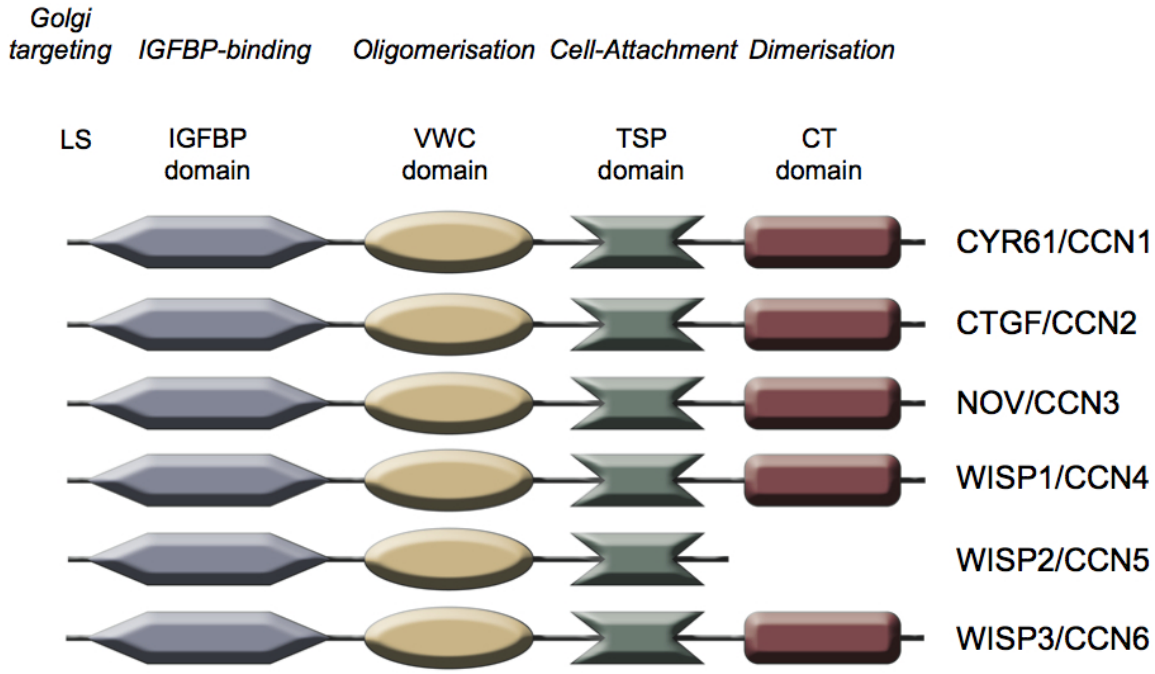

Figure 2.1.: *Modular structure of the CCN protein family. CCN1-CCN6 share up to four structural domains with amino acid sequence identy of 38–98% within individual modules. Full-length WISP2/CCN5 is lacking the fourth module, the CT domain. Bioactive forms of CCN1, -2, -3, -4 and -6, lacking one or more of the structural domains, have also been reported.*

regulatory system, in which one member drives a process while a closely related member can inhibit the same process. Several studies illustrate that the function of an individual CCN protein is also tissue specific and may even be contrary in different target cells. Factors that allow this cell- specificity are based on interactions of these proteins with a variety of components of the ECM, thereby providing a link to the cell surface (Yeger and Perbal 2007). Noticeable, during the last ten years all CCN members received more and more attention in the research field comprising the musculoskeletal system. The main focus is indeed located to the well-studied and first identified CCN members (CCN1-3). But also the WISP proteins (CCN4-6) rouse higher interest concerning regulations during the differentiation of bone marrow derived human mesenchymal stem cells (hMSCs) as well as bone formation and fracture repair (French et al. 2004; Schuetze et al. 2005).

CHAPTER
THREE

SPECIAL VIEW ON THE CCN FAMILY MEMBERS: WISP1-3

3.1. Constitution and homologies

Human WISP proteins (WISP1-3) were all identified by Pennica et al. (1998). WISP1 and -2 were clearly assigned as WNT1-induced genes in the mammary epithelial cell line C57MG. They were allocated to the CCN family in 2003 and renamed in CCN4/WISP1, CCN5/WISP2 and CCN6/WISP3 (Brigstock 2003). Figure 3.1 illustrates the encoded amino acid sequence alignment of the three human WISP proteins. On close examination, it is conspicuous that the four modules show distinct homologies as well as clear differences in their sequence. The N-terminal domain contains a consensus sequence (GCGC-CXXC) conserved in most insulin-like growth factor binding proteins (IGFBP). This sequence is present in WISP2 and -3, whereas WISP1 has a glutamine in the third position instead of a glycine (Pennica et al. 1998). The second module, the VWC domain, which is thought to participate in protein complex formation and oligomerization (Mancuso et al. 1989), contains less conserved cysteine residues in WISP3 than in WISP1 and -2. Between the VWC and TSP domains is a highly variable sequence of amino acids, which acts as a molecular hinge and is susceptible to proteolytic degradation by matrix metalloproteinases (Hashimoto et al. 2002). And in the end, the CT domain, which is involved in dimerization and receptor binding (Voorberg et al. 1991) and is completely absent in WISP2.

3.2. Mode of function in the musculoskeletal system

Within the musculoskeletal system, previous studies showed that WISP2 and -3 are expressed during the chondrogenic, osteogenic and adipogenic differentiation of MSCs (Schuetze et al. 2005), therefore indicating a central role during development and bone formation. French et al. (2004) demonstrated also the role of WISP1 as an osteogenic potentiating factor, promoting MSC proliferation and osteoblastic differentiation as well as repressing chondrocytic differentiation. Additional data regarding osteogenic differentiation indicate a correlation of WISP1 with bone morphogenetic protein-signalling (Ono et al. 2011) and transforming growth factor-signalling (Inkson et al. 2008). Concerning protein interactions, the major binding partners for WISP1 are the ECM-associated proteoglycans decorin and biglycan (Desnoyers et al. 2001). Inkson et al. (2009) described the interaction between WISP1 and biglycan by showing that WISP1 abrogates the repression of proliferation in bone marrow stromal cells, previously induced by biglycan. Furthermore, a prominent role of WISP1 in experimental and human osteoarthritis (OA) has been suggested from gene expression studies (Blom et al. 2009) and the association of a single nucleotide polymorphism with OA (Urano et al. 2007).

Figure 3.1.: *Encoded amino acid sequence alignment of human WISP1-3. Identities are visualized with bold letters. WISP1 and -3 are most similar (42% identity), whereas WISP2 has 37% identity with WISP1 and 32% identity with WISP3. Conserved cysteine residues are marked with stars. Domains (insulin-like growth factor-binding protein (IGFBP), von Willebrand factor type C (VWC), thrombospondin (TSP), and C-terminal (CT)) are underlined and labelled correspondingly.*

WISP2 is the least studied protein of the CCN family in relation to functional properties within the musculoskeletal system. Its expression seems to be donor dependent in hMSCs and completely depleted in different osteoblast, osteosarcoma and chondrocyte cell lines (Chap. 8). These findings are in line with the observations of Schuetze et al. (2005), who described a decreased expression of WISP2 during the chondrogenic- and adipogenic differentiation of MSCs. The declined expression of WISP2 during adipogenesis could be explained by the negative regulation of adipocyte differentiation through WNT-signalling (Ross et al. 2000). WISP2 is a known down-stream target of the WNT-signalling cascades and its expression is clearly enhanced after WNT1-activation (Longo et al. 2002; Pennica et al. 1998).

WISP3 is exceptional within the CCN family of proteins, since it represents the only CCN protein that is directly linked to a human disease in a causal manner. Inactivating frameshift- and nonsense mutations in exons 1, 2 and 5 of the human WISP3 gene were identified and clearly associated with the hereditary disease Progressive Pseudorheumatoid Dysplasia (PPD) (Hurvitz et al. 1999). This initial finding was confirmed by a number of additional case-studies indicating a potential role of WISP3 for cartilage homeostasis (Delague et al. 2005; Ehl et al. 2004). Recently, studies that investigated gain and loss of function in the zebrafish model revealed that WISP3 appears to be able to modify bone morphogenetic protein and WNT-signalling. With that, it influenced pharyngeal cartilage size and shape in development (Nakamura et al. 2007). A possible role of WISP3 in cartilage is supported from studies using a C28I2 derivative chondrogenic cell line that over-expresses WISP3. The up-regulation of collagen type II and aggrecan expression via the SOX9 pathway indicated a potential role of WISP3 for cartilage differentiation (Sen et al. 2004). Superoxide dismutase expression and activity was promoted both by recombinant WISP3 treatment and WISP3 transduction of C28I2 chondrocytes (Davis et al. 2006).

3.3. WISP1 and its connection to cell survival

Despite these findings, the role of WISP proteins in cartilage and cells of the musculoskeletal system is widely unknown, but several working groups depict WISP1 as an important survival factors in a variety of cells types. In this regard, Su et al. (2002) documented first the importance of WISP1 for the cell survival of rat kidney fibroblasts. WISP1 thereby leads to phosphorylation and activation of the survival factor v-akt murine thymoma viral oncogene homolog (AKT), which is known to promote cell survival by inactivation of BCL2-associated agonist of cell death (BAD) and caspase 9 (CASP9) (Cardone et al. 1998; Datta et al. 1997; Zha et al. 1996). Additional, Su et al. (2002) discovered in human lung carcinoma cells (H460 cells) that WISP1 might affect p53 induced apoptosis after DNA damage. It seems that WISP1 has the ability to block cytochrome c release and thus prevent the assembly of the apoptosome and subsequent cleavage of the effector caspase 3 (CASP3). The importance of WISP1 in p53 dependent cell death by preventing the release of cytochrome c in the cytosol, was also confirmed by recent studies using anthracycline antibiotic doxorubicin (DOX), a potent cancer chemotherapeutic agent. DOX induced cell death in adult mouse cardiomyocytes is attenuated by pretreatment with WISP1 (Venkatesan et al. 2010). WISP1 inhibits DOX mediated p53 activation and furthermore decreases the mitochondrial translocation of BCL2-associated X protein (BAX). Additionally, WISP1 reverses DOX-induced suppression of the survival factors B-cell CLL/lymphoma 2 (BCL2), BCL2-like 1 (BCLXL) and AKT.

CHAPTER
FOUR

AIM OF THE STUDY

Based on their correlation with the WNT-signalling pathway and their known interactions with molecules of the ECM, WISP proteins achieve more and more attention in research areas of tissue engineering and regenerative medicine. These characteristics wakened the interest concerning these proteins in our working group. In this thesis, we focus on molecular backgrounds concerning consequences of WISP-signalling in primary cells (hMSCs) and different cell lines connected to the musculoskeletal system. Hereby, our major goals are to:

1. identify natural expression of WISP1 (two transcript variants) and WISP2 in a variety of musculoskeletal cell types, i.e. hMSCs, osteoblasts and chondrocytes.

2. establish necessary molecular and cell biological tools to measure and analyze whole genome expression in different conditions, like recombinant protein production and knock-down approaches.

3. examine WISP-signalling and associated regulatory processes in detail after gene-silencing within naturally expressing tissues.

4. examine WISP-signalling and associated regulatory processes by treatment of gene-silenced cells with recombinant protein.

To dissect these molecular mechanisms, (1) RT-PCR analyses were performed to confirm a native expression of WISP1 and -2 in different cells of the musculoskeletal system. (2) This study comprised the production of recombinant (r)proteins of WISP1-T1 and -T2 and WISP2. Furthermore, a forced reduction of the endogenous protein expression was achieved by gene-silencing with different shRNA constructs, confirmed by subsequent RT-PCR analyses. (3) Genome-wide microarrays, taken shortly after down-regulation of WISP1 expression, were compared to control chips (cells treated with scrambled constructs) to examine global gene expression patterns. A bioinformatical workflow has been developed for this purpose. Several highly ranked candidates of regulated genes were selected for validation with RT-PCR. (4) Subsequent to a successful down-regulation of a given native WISP1 expression, cells were partially treated with rWISP1-T1 and -T2. Untreated and treated cells were compared by microscopic essays and isolated mRNA was used for microarray analyses. Further, we examined self-regulation of WISP1-T1, -T2 and WISP2 with RT-PCR of treated and untreated cells.

With this thesis we intend to counter the lack of knowledge about the general importance of WISP-signalling within the musculoskeletal system by a variety of molecular and cell biological methods. The project will thereby contribute to a better understanding of the potential of WISP-associated signalling for cartilage homeostasis and could provide new options for maintenance and regeneration of cartilage.

Materials and Methods

CHAPTER
FIVE

MATERIALS

5.1. Consumables

Table 5.1.: *Listed are all utilized consumables with their corresponding suppliers.*

Consumables	**Supplier**
Autoradiography films	Fuji, purchased from A. Hartenstein GmbH, Würzburg, Germany
Blotting paper	Schleicher & Schuell, purchased from A. Hartenstein GmbH, Würzburg, Germany
Cell culture flasks (175cm^2)	Greiner Bio-One GmbH, Frickenhausen, Germany
Cell culture flasks (25cm^2, 75cm^2, 150cm^2)	TPP, Biochrom AG, Berlin, Germany
Cell scraper	SPL Lifesciences, purchased from A. Hartenstein GmbH, Würzburg, Germany
Cell strainers	BD Falcon, purchased from A. Hartenstein GmbH, Würzburg, Germany
Centrifugation tubes (15ml, 50ml)	Greiner Bio-One GmbH, Frickenhausen, Germany
Cryo.s^{TM}(2ml)	Greiner Bio-One GmbH, Frickenhausen, Germany
Eppendorf micro test tubes	Greiner Bio-one GmbH, Frickenhausen, Germany
GeneChip HG-U 133 Plus 2.0	Affymetrix UK Ltd., High Wycombe, UK
HiTrap^{TM}Protein G HP columns	GE Healthcare Europe GmbH, München, Germany
Lab-Tek Chamber Slides	Nunc, purchased from A. Hartenstein GmbH, Würzburg, Germany
Multitips	Eppendorf AG, purchased from A. Hartenstein GmbH, Würzburg, Germany

...continues on next page

Table 5.1.: *(...continued)*

Consumables	Supplier
NucleoSEQ columns	Macherey-Nagel GmbH & Co. KG, Düren, Germany
Pasteur pipettes	A. Hartenstein GmbH, Würzburg, Germany
PCR reaction tubes	Greiner Bio-one GmbH, Frickenhausen, Germany
Pipette tips	Brandt, purchased from Laug & Scheller GmbH, Kürnch, Germany
Pipette tips, aseptic	Becton Dickinson, USA, purchased from A. Hartenstein GmbH, Würzburg, Germany
Plastik pipettes (5ml, 10ml, 25ml)	Greiner Bio-One GmbH, Frickenhausen, Germany
Plates (6-, 12-, 24well)	Greiner Bio-One GmbH, Frickenhausen, Germany
Protran nitrocellulose transfer membrane	Whatman Schleicher & Schuell, purchased from A. Hartenstein GmbH, Würzburg, Germany
PVDF blotting membran	Whatman GmbH, purchased from A. Hartenstein GmbH, Würzburg, Germany
Sequencing sample tubes	Applied Biosystems Applera Deutschland GmbH, Darmstadt, Germany
Sterile filters	Carl Roth GmbH & Co. KG, Karlsruhe, Germany
UVettes	Eppendorf AG, purchased from A. Hartenstein GmbH, Würzburg, Germany
Whatman paper	Whatman GmbH, purchased from A. Hartenstein GmbH, Würzburg, Germany

5.2. Chemicals and reagents

Table 5.2.: *Listed are all utilized chemicals and reagents with their corresponding suppliers.*

Chemicals and reagents	Supplier
1,4-Dithiothreitol (DTT)	Roche Diagnostics GmbH, Mannheim, Germany
2-Mercaptoethanol	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany

...continues on next page

Table 5.2.: *(...continued)*

Chemicals and reagents	**Supplier**
2-Propanol	Carl Roth GmbH & Co. KG, Karlsruhe, Germany
Acetic acid	Carl Roth GmbH & Co. KG, Karlsruhe, Germany
Acetone	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
Agar	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
Agarose multi-purpose	Bioline GmbH, Luckenwalde, Germany
Albumin from bovine serum (BSA)	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany
Ammonia solution (25%)	Merck KGaA, Darmstadt, Germany
Ammonium persulfate (APS)	PAA Laboratories GmbH, Pasching, Austria
Ampicillin	Carl Roth GmbH & Co. KG, Karlsruhe, Germany
BacPAK complete Medium	Takara Bio Europe/Clontech, Saint-German-en-Laye, France
BacPAK Grace‘s Basic Medium	Takara Bio Europe/Clontech, Saint-German-en-Laye, France
Biozym LE Agarose	Biozym Scientific GmbH, Hessisch-Oldendorf, Germany
Boric acid	Merck KGaA, Darmstadt, Germany
Bromphenol blue sodium salt	Carl Roth GmbH & Co. KG, Karlsruhe, Germany
Citric acid anhydrous	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
Colored reaction buffer (5x)	Bioline GmbH, Luckenwalde, Germany
Complete protease inhibitor cocktail	Roche Diagnostics GmbH, Mannheim, Germany
Developer	Kodak, purchased from A. Hartenstein, Würzburg, Germany
Dexamethasone	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany
Dimethyformamide	Carl Roth GmbH & Co. KG, Karlsruhe, Germany
Dimethylsulfoxide (DMSO)	Carl Roth GmbH & Co. KG, Karlsruhe, Germany
DMEM/HAMs F-12 with L-Glutamine	PAA Laboratories GmbH, Pasching, Austria

Table 5.2.: *(...continued)*

Chemicals and reagents	**Supplier**
DNA ladder (1kb)	PEQLAB Biotechnology GmbH, Erlangen, Germany
DNA ladder plus (100bp)	PEQLAB Biotechnology GmbH, Erlangen, Germany
Dulbecco's phosphate buffered saline (PBS) powder	Biochrome AG, Berlin, Germany
Ethanol (100%)	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
Ethanol (98%, denatured)	Carl Roth GmbH & Co. KG, Karlsruhe, Germany
Ethidium bromide	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
Ethylenediaminetetraacetic acid (EDTA)	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
Fetal calf serum (FCS)	PAA Laboratories GmbH, Pasching, Austria
Fixer	Kodak, purchased from A. Hartenstein, Würzburg, Germany
Glycerol 2-phosphat disodium salt hydrate	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany
Glycerol	Merck KGaA, Darmstadt, Germany
Glycine	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
Heparin sodium salt	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany
Hexadimethrine bromide (polybrene)	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany
Horse serum	PAA Laboratories GmbH, Pasching, Austria
HPLC-H_2O	Carl Roth GmbH & Co. KG, Karlsruhe, Germany
Hydrochloric acid (1M)	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
Insect Express Sf9-S2 Medium	PAA Laboratories GmbH, Pasching, Austria
LE agarose	Biozym Scientific GmbH, Hessisch-Oldendorf, Germany
L-Ascorbic acid 2-phosphate	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany
Lipofectamine 2000	Invitrogen GmbH, Darmstadt, Germany
Loading dye (6x)	Peqlab Biotechnology GmbH, Erlangen, Germany

Chemicals and reagents	**Supplier**
Magnesium chloride	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
MitoTracker®Red	Invitrogen GmbH, Darmstadt, Germany
Methanol	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
N,N,N-N-tetramethylethylene-diamine (TEMED)	Merck KGaA, Darmstadt, Germany
NE Buffer (10x)	New England Biolabs GmbH, Frankfurt, Germany
Penicillin/Streptomycin	PAA Laboratories GmbH, Pasching, Austria
Ponceau S solution	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany
Pyruvate	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany
Rainbowmarker RPN 800	GE Healthcare Europe GmbH, München, Germany
Random hexamer primers	Invitrogen GmbH, Darmstadt, Germany
Roti-Quant (5x)	Carl Roth GmbH & Co. KG, Karlsruhe, Germany
Rotiphorese gel 40 acrylamide/bisacrylamide mix	Carl Roth GmbH & Co. KG, Karlsruhe, Germany
Skim milk powder	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
S.O.C medium	Invitrogen GmbH, Darmstadt, Germany
Sodium acetate	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
Sodium chloride	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
Sodium dodecyl sulfate (SDS)	Merck KGaA, Darmstadt, Germany
Sodium hydroxide pellets	Merck KGaA, Darmstadt, Germany
Sodium hydroxide solution (1N)	AppliChem, purchased from A. Hartenstein GmbH, Würzburg
Template Suppression Reagent (TSR)	Applied Biosystems Aplera Deutschland GmbH, Darmstadt, Germany
Tris-Hydrochlorid (99%)	Carl Roth GmbH & Co. KG, Karlsruhe, Germany

Table 5.3.: *(...continued)*

Equipment	**Supplier**
CO_2 incubator CB 150	Binder GmbH, Tuttlingen, Germany
CO_2 incubator Kelvitron T	Thermo Electron LED GmbH, Langenselbold, Germany
Dishwasher	Miele &Cie. KG, Gütersloh, Germany
Drier	Thermo Electron LED GmbH, Langenselbold, Germany
Freezer Economic (-20°C)	Bosch GmbH, Gerlingen-Schillerhöhe, Germany
Freezer II Shin (-80°C)	Nunc GmbH & Co. KG, Wiesbaden, Germany
Fridge Freshcenter	Bosch GmbH, Gerlingen-Schillerhöhe, Germany
Gel elektrophoresis Mini Protean 3cell	Bio-Rad Laboratories GmbH, München, Germany
Glas jars	Schott, purchased from A. Hartenstein, Würzburg, Germany
Glas pipettes	A. Hartenstein, Würzburg, Germany
Heater	Medax, purchased from A. Hartenstein, Würzburg, Germany
Heat shaker TH15	Edmund Bühler GmbH, Hechingen, Germany
Laminar air flow box Hera Safe KS12	Thermo Electron LED GmbH, Langenselbold, Germany
Magnetic stirrer	A. Hartenstein, Würzburg, Germany
Microskope Axiovert 25	Carl Zeiss Jena GmbH, Jena, Germany
PerfectBlue semi-dry electroblotter	PEQLAB Biotechnologie GmbH, Erlangen, Germany
PH meter inolab ph level 1	WTW, purchased from A. Hartenstein, Würzburg, Germany
Pipetboy Acu	IBS Integra Biosciences, Fernwald, Germany
Power Pac 300	Bio-Rad Laboratories GmbH, München, Deutschland
Precision balance SPO51	Scaltec Instruments, purchased from A. Hartenstein, Würzburg, Germany
Radiographic hypercassette	Amersham Lifesciences, purchased from A. Hartenstein, Würzburg, Germany

...continues on next page

Table 5.3.: *(...continued)*

Equipment	Supplier
Sequencer ABI PRISM 310	Applied Biosystems Applera Deutschland GmbH, Darmstadt, Germany
Sonificator Sonoplus	Bendelin Electronic GmbH &. Co KG, Berlin, Germany
Single channel pipette	Abimed, Langenfeld, Germany
Speed Vac SC 110	Savant, Thermo Electron LED GmbH, Langenselbold, Germany
Thermal cycler PTC-200	Peltier, MJ Research, purchased from Biozym Scientific GmbH, Hessisch Oldendorf, Germany
Thermal printer Seico	LTF Labortechnik GmbH & Co. KG, Wasserburg, Germany
Vortexer Vortex-Genie 2	Scientific Industries, purchased from A. Hartenstein, Würzburg, Germany
Water bath WB7	Memmert, purchased from A. Hartenstein, Würzburg, Germany

5.4. Kits

Table 5.4.: *Listed are all utilized kits with their corresponding suppliers.*

Kits	Supplier
BacPAK^{TM}Baculovirus Expression System	Takara Bio Europe/Clontech, Saint-German-en-Laye, France
Big Dye Terminator v1.1 Cycle Sequencing	Applied Biosystems Aplera Deutschland GmbH, Darmstadt, Germany
dNTP Set (100mM)	Bioline GmbH, Luckenwalde, Germany
ECL Plus Detection	Amersham, purchased from GE Healthcare Europe GmbH, München, Germany
Fast-Link DNA Ligation	Biozym Scientific GmbH, Hessisch-Oldendorf, Germany

...continues on next page

Table 5.4.: *(...continued)*

Kits	Supplier
Lentiviral Expression System	Open Biosystems, Inc., Fisher Scientific GmbH, Schwerte, Germany
NucleoSpin extract II (PCR clean-up gel extraction)	Macherey-Nagel GmbH & Co. KG, Düren, Germany
NucleoSpin plasmid purification (mini preparation)	Macherey-Nagel GmbH & Co. KG, Düren, Germany
NucleoSpin RNA II (RNA/protein extraction)	Macherey-Nagel GmbH & Co. KG, Düren, Germany
PlusOne™Silver Staining Kit, protein	Amersham, purchased from GE Healthcare Europe GmbH, München, Germany
PureYield plasmid midi preperation	Promega GmbH, Mannheim, Germany
Sulforhodamine FLICA™	Immunochemistry Technologies, Bloomington, USA
TOPO TA cloning	Invitrogen GmbH, Darmstadt, Germany

5.5. shRNA target sets

Table 5.5.: *Listed is a set of five different shRNA constructs and one shRNA scrambled negative control, commercially supplied from the RNAi Consortium (TRC) of Thermo Fisher Scientific (Open Biosystems, Inc., Fisher Scientific GmbH, Schwerte, Germany). The shRNA constructs include a hairpin of 21bp (sense and antisense) linked with a loop of 6bp. Each hairpin was cloned into the lentiviral vector pLKO.1.*

Name	Oligo ID	Homology	Sequence ID
shRNA1	TRCN0000033349	Homo sapiens	NM_003882, NM_080838
shRNA2	TRCN0000033350	Homo sapiens	NM_003882, NM_080838
shRNA3	TRCN0000033351	Homo sapiens	NM_003882, NM_080838
shRNA4	TRCN0000033352	Homo sapiens	NM_003882, NM_080838
shRNA5	TRCN0000033353	Homo sapiens	NM_003882, NM_080838

Hairpin sequences of shRNA constructs:

shRNA1: 5' -CCGGGCATCCATGAACTTCACACTTCTCGAGAAGTGTGAAGTTCATGGATGCTTTTTG- 3'

shRNA2: 5' -CCGGCCACTCGGATCTCCAATGTTACTCGAGTAACATTGGAGATCCGAGTGGTTTTTG- 3'

shRNA3: 5' -CCGGCTGTGGAGTTTGCATGGACAACTCGAGTTGTCCATGCAAACTCCACAGTTTTTG- 3'

shRNA4: 5' -CCGGCCACTCGGATCTCCAATGTTACTCGAGTAACATTGGAGATCCGAGTGGTTTTTG- 3'

shRNA5: 5' -CCGGGCTTCTGTAACCTGAGCTGTACTCGAGTACAGCTCAGGTTACAGAAGCTTTTTG- 3'

Hairpin sequences of shRNA scrambled negative control:

5' -CCGGCCTAAGGTTAAGTCGCCCTCGCTCGAGCGAGGGCGACTTAACCTTAGGTTTTTG- 3'

5.6. Enzymes

Table 5.6.: *Listed are all utilized enzymes with their corresponding suppliers.*

Enzymes	**Supplier**
Bioscript™ reverse transcriptase	Bioline GmbH, Luckenwalde, Germany
Calf intestine alkaline phosphatase (CIAP)	Invitrogen GmbH, Darmstadt, Germany
DNA polymerase Biotaq™	Bioline GmbH, Luckenwalde, Germany
DNA polymerase Mango Taq™	Bioline GmbH, Luckenwalde, Germany
DNA polymerase Pfx50™	Invitrogen GmbH, Darmstadt, Germany
Restriction enzyme AgeI	New England Biolabs GmbH, Frankfurt, Germany
Restriction enzyme BsrGI	New England Biolabs GmbH, Frankfurt, Germany
Restriction enzyme EcoRI	New England Biolabs GmbH, Frankfurt, Germany
Restriction enzyme EcoRV	New England Biolabs GmbH, Frankfurt, Germany
Restriction enzyme NcoI	New England Biolabs GmbH, Frankfurt, Germany
Restriction enzyme NotI	New England Biolabs GmbH, Frankfurt, Germany
Restriction enzyme Xho	New England Biolabs GmbH, Frankfurt, Germany
Trypsin (10x)	PAA Laboratories GmbH, Pasching, Austria
Trypsin-EDTA (1x)	PAA Laboratories GmbH, Pasching, Austria

5.7. Antibodies

Table 5.7.: *Listed are all utilized antibodies with their corresponding suppliers.*

Antibodies	**Supplier**
Goat anti-rabbit IgG-peroxidase sec. antibody, (A4174)	Sigma-Aldrich Chemie GmbH, Steinheim, Germany
Goat anti-rabbit IgG-FITC sec. antibody, (sc-2012)	Santa Cruz Biotechnology Inc., Heidelberg, Germany
Mouse anti-cytochrome c prim. antibody, 6H2.B4 (556432)	BD Biosciences, Heidelberg, Germany
Rabbit anti-Fc-tag prim. antibody, custom made (216)	ImmunoGlobe GmbH, Himmelstadt, Germany
Rabbit anti-mouse IgG-FITC sec. antibody, (F-0261)	DakoCytomation, Copenhagen, Denmark
Rabbit anti-p53 prim. antibody, FL-393 (sc-6243)	Santa Cruz Biotechnology Inc., Heidelberg, Germany

5.8. Competent cells

Table 5.8.: *Listed are all utilized competent cells with their corresponding suppliers.*

Competent cells	**Supplier**
One Shot®Stbl3™	Invitrogen GmbH, Darmstadt, Germany
One Shot®TOP 10 cells (TOPO TA Cloning Kit)	Invitrogen GmbH, Darmstadt, Germany
XL-10 GOLD	Stratagene, Waldbronn, Germany

5.9. cDNA clones

Table 5.9.: *Listed are all utilized cDNA clones with their corresponding suppliers.*

cDNA clones	Supplier
WISP1-T1 (full-length clone IOH42456)	ImaGenes GmbH, Berlin; Germany
WISP1-T2 (full-length clone)	ImaGenes GmbH, Berlin; Germany
WISP2 (full-length clone)	ImaGenes GmbH, Berlin; Germany

5.10. Plasmids

Table 5.10.: *Listed are all utilized plasmids with their corresponding suppliers.*

Name	Size (bp)	Supplier
TOPO pCR2.1 cloning vector	3900	Invitrogen GmbH, Darmstadt, Germany
pLKO.1-puro cloning vector	8901	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany
pLKO.1-puro control vector	7052	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany
pLKO.1-puro non-target shRNA	7086	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany
pLKO.1-puro turbo GFP control plasmid	8347	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany
psPAX2 packaging plasmid	10703	Addgene Inc., Cambridge, USA
VSV-G/pMD2.G	5824	Addgene Inc., Cambridge, USA

5.11. Primers

Primers were designed using the free online software Primer3Plus (Rozen and Skaletsky 2000) and commercially supplied by Eurofins MWG GmbH, Ebersberg, Germany. Intron spanning primer pairs were chosen (when possible) to obviate genomic DNA impureness within the samples.

Table 5.11.: *Listed are all sequences of primers used for open reading frame amplification of WISP1-T1, WISP1-T2 and WISP2. Columns (from left to right) describe primer sequence, annealing temperature (T_A), PCR product size (S_P) in base pairs (bp) and the sequence ID of the corresponding gene product.*

	Primer sequence	T_A [°C]	S_P (bp)	Sequence ID
WISP1-T1 (WNT1 inducible signalling pathway protein 1)

CHAPTER
SIX

METHODS

6.1. Cell culture

6.1.1. Isolation of primary human mesenchymal stem cells (hMSCs)

Human bone marrow derived stem cells were isolated from the femoral head obtained from patients undergoing total hip arthroplasty. This occurs under the approval of the Local Ethics Committee of the University of Würzburg. Each patient was informed and provided a written consent. Donors were aged between 43 and 79 years (in average 64.5). Trabecular bone pieces were harvested, mixed with DMEM Ham's F12 medium and strongly vortexed. After centrifugation (1200rpm/5min) the cell pellet was reconstituted in DMEM Ham's F12 medium supplemented with 10% foetal bovine serum (FCS), antibiotics (50 I.U. penicillin/ml and 50μg streptomycin/ml) and 50μg/ml ascorbate (complete medium). After repeated washing and vortexing, the stromal cells containing medium was filtered through a cell strainer to hold back bone fragments. The released cells were pelleted, suspended in complete medium and plated at a density of 2x10^8 cells per 150cm^2 tissue culture flask. Previously, cell number and vitality was determined by mixing 50μl cell suspension and 50μl trypan blue. A Neubauer counting chamber was used to determine the cell density (Lindl 2002). Seeded cells were incubated at 37°C in a humidified atmosphere enriched with 5% CO_2. Non-adherent cells were removed after two days and subsequently the medium was changed every three to four days until the cell cultures reached 90-100% confluence.

6.2. Culture and propagation of primary cells and cell lines

6.2.1. Subculturing

Culture medium was replaced every second-third day until the cells reached 90-100% confluence. Subsequently, cells were washed with PBS and detached by exposure of 1x trypsin/EDTA for 3-7min at 37°C. The addition of culture medium after exposure time was necessary to inactivate trypsin activity. Cells were pelleted by centrifugation (1200rpm for 5min), resuspended in fresh culture medium and subcultured at the specific ratio (Tab. 6.1). For experimental settings, plating density depended on the further applications of the cells (see next sections).

Table 6.1.: *Summary of derivation and cultivation conditions of primary cells and cell lines.*

Name	Derivation	Subculturing (split ratio)	Temp. [°C]
C28I2	human (rib cartilage)	1:30	37, 32 [1]
HEK-293T	human (embryonic kidney)	1:8	37
hFOB	human	1:6	37
hMSC	human (bone marrow)	1:3	37
hTert4	human	1:4	37
hTert20	human	1:20	37
MG63	human (ostesarcoma)	1:30	37
SF21	insect (Spodoptera frugiperda)	1:2 - 1:10	37
TE85	human (ostesarcoma)	1:30	37
Tc28a2	human (rib cartilage)	1:30	37, 32 [1]
U2	human (ostesarcoma)	1:30	37

Depending on culture vessel size, different quantities of cell culture medium, PBS and 1x trypsin/EDTA were required (Tab. 6.2).

Subculturing SF21 cells

Culture medium was replaced every seven days until the cells reached nearly 90% confluence. To divide subcultures, used medium was removed and cells were scraped and mixed in fresh culture medium. The split ratio extended between 1:2 and 1:10. For experimental setting, cells were disseminated in Insect express SF9 medium.

6.3. Recombinant protein production

Recombinant (r)protein production describes the method of generating protein expressions that have been produced by recombinant DNA techniques. For this purpose, proteins were created through combining sequences that would not occur via the common process of gene splicing. Genes of interest were amplified and integrated into plasmids, which were used as viral vectors to reproduce the altered DNA by replication and infection of other cells. This increased the amount of cells with the recombinant DNA and enabled an efficient (r)protein

[1] cells were incubated at 32°C during experimental settings

Table 6.2.: *Summary of appropriate cell culture vessel types and their corresponding amount of culture medium, PBS and 1x trypsin/EDTA.*

Culture vessel	**Culture medium [ml]**	**PBS [ml]**	**1x trypsin/EDTA [ml]**
6 well (9,03cm^2)	3-5	1	0.5
25cm^2 flask	5	2	1
75cm^2 flask	15	10	4
150cm^2 flask	25	12	5
175cm^2 flask	30	15	6
chamber slide (4.2cm^2)	1.2 - 2.0	0.5	-
chamber slide (1.8cm^2)	0.5 - 0.9	0.25	-

production. In this study, (r)protein expression was achieved with the Baculovirus Expression System purchased from Clontech. Baculoviruses are a family of viruses that infect mostly moth species and the virus autographa californica nuclear polyhedrosis (AcMNPV) is commonly used to express foreign proteins in the insect cell line SF21, developed from the moth Spodoptera frugiperda. The stable integration of the target sequence in the virus genome was caused by gene replacement, encoding the polyhedrin protein p10, which is not useful for the virus in cell culture. The polyhedrin promotor induced a high-level transcription of the insert, resulting in an increased amount of (r)protein.

6.3.1. Proof-reading Polymerase chain reaction (PCR)

Full-length cDNA plasmid sequences of WISP1-T1, WISP1-T2 and WISP2 were amplified with the Pfx50^{TM}DNA Polymerase, containing a proof-reading 5' to 3' exonuclease activity in the provided buffer system. Pfx50^{TM}DNA Polymerase produces PCR products, which can be directly used for TOPO®Cloning. Specific primer pairs (Sec. 5.11) were designed containing restriction sites for XhoI (forward primer) and EcoRI (reverse primer) flanking the expected open reading frames of the three different cDNA clones. According to the manufacturer's instructions 1-100pg cDNA template was applied in three different dilutions (1:10, 1:100, 1:1000) to separated PCR reactions. Standard protocol and reaction steps for the PTC-200 thermal cycler purchased from Peltier MJ Research are listed in table 6.3. Subsequently, proof-reading PCR products were verified by gel electrophoresis and sequencing analyses (Subsec. 6.3.2 and 6.3.3).

6.3.2. Gel electrophoresis

Agarose gel electrophoresis was used to determine the presence of PCR products as well as RNA fragments and plasmid inserts. DNA (or RNA) was forced to migrate through a highly

Table 6.3.: *Standard reaction steps: proof-reading PCR*

HPLC water	50			

cross-linked agarose matrix in response to an electric current with a voltage of 0.9 V/cm^2 agarose gel. Phosphates on the DNA are negatively charged and therefore migrate to the positive pole. 1-1.8% agarose gels were prepared by dissolving agarose powder in 0.5xTBE buffer. For visualisation, 5% ethidium bromide was added to the solution. It intercalates into double-stranded DNA or RNA and fluoresces when exposed to UV-light. After the gel polymerised at room temperature (RT), proof-reading PCR products, plasmid DNA and RNA were enriched with 1xloading dye and loaded onto the gel. cDNA PCR products were achieved with the MangoTaq^{TM}DNA polymerase and contained already a loading dye in the associated buffer system (Subsec. 6.4.5). Depending on the target DNA or RNA size, a 100bp or 1000bp ladder was used to verify the expected size. Small fragments run more quickly than large fragments at a rate proportional to their size and were visualized by exposure to UV-light in a UV-chamber. Transcript amounts were normalized with the housekeeping gene EF1α and evaluated with the densitometric software GelAnalyzer 2010a.

6.3.3. Sequencing analysis

DNA sequencing is a method to verify the precise sequence of nucleotides (dNTPs) in a sample of DNA. Dideoxy sequencing (Sanger's method or chain termination) is based on the use of dideoxynucleotides (ddNTP's) additional to the normal dNTPs during PCR. Each of the different ddNTPs (ddATP, ddCTP, ddGTP, and ddTTP) is labelled with a distinct fluorescent dye and contains a hydrogen group on the 3' carbon instead of a hydroxyl group. After integration into a new sequence a phosphodiester bond cannot accumulate between the ddNTP and the next incoming dNTP. This results in termination of DNA synthesis and generates fragments of random length. All sequencing analyses were performed with the ABI PRISM 310 Sequencer purchased from Applied Biosystems. The appropriate Big Dye Terminator v1.1 Cycle Sequencing Kit includes dye terminators, dNTPs, AmpliTaq DNA Polymerase, magnesium chloride and buffer. According to the manufacturer's instruction a PCR mix was generated containing 5pmol primer (forward or reverse) and 1-2μl PCR product or 100-150ng plasmid DNA per reaction. Standard PCR reaction steps for the PTC-200 thermal cycler are listed below in table 6.4.

Table 6.4.: *Standard reaction steps: sequencing analysis PCR*

Reaction steps	**Temp. [°C]**	**Time [min]**
Initial denaturation	94	4
Denaturation	94	0.5
Annealing	50	1
Elongation	60	1
Final elongation	72	5
Cooling	12	inf

The amplification products were loaded onto NucleoSeq columns and excess of salts, nucleotides and primers were retained through centrifugation, whereas the eluate contained the pure PCR product. 0.1M sodium acetate (pH 4.3) supplemented to 80% ethanol precipitated the DNA. After incubation at room temperature (15min) and centrifugation (13.000rpm for 20min), the pellet was washed with 70% ethanol and air-dried. The pellet was then resuspended in 15-30μl Template Suppression Reagent and denaturated at 94°C for 4min. Subsequently, the samples were chilled on ice for a few minutes and placed into the sequencer. A laser determined the identity of each band, since the four dyes fluorescence at different wavelength. Using the ABI PRISM 310 collection and Sequencing analysis 3.4 software, the results were depicted in form of a chromatogram of coloured peaks that correspond to the nucleotide in that location in the DNA. In conclusion, sequences were compared to the online database of NCBI by inserting into NCBI blast search.

6.3.4. TOPO®Cloning

The plasmid vector pCR®2.1-TOPO®(purchased from invitrogen) is based on the properties of the enzyme topoisomerase I to cleave and rejoin supercoiled DNA ends and facilitate replication. This enzyme specifically recognizes the sequence 5'-C/TCCTT-3' (Shuman 1991), which present the final bases at both ends of the linearized vector. The enzyme is covalently attached with its tyrosyl residue (Tyr-274) and the 3' phosphate of the cleaved strands.

Ligation of WISP1-T1, WISP1-T2 and WISP2 PCR products

Full-length cDNA sequences of WISP1-T1, WISP1-T2 and WISP2 were amplified with the Pfx50^{TM}DNA polymerase. Pure PCR product and salt solution (1μl of each) were diluted in 3μl HPLC water and subsequently mixed with 1μl of linearized pCR®2.1-TOPO®vector. During the incubation (5min, RT), the free 5' ends of the PCR product strands were ligated (catalysed by topoisomerase I) with the topoisomerase/3' end of each vector strand. Subsequently, the reaction was stored on ice until the transformation of the ligated vector into chemically competent E.coli cells was performed.

Transformation into chemically competent cells

Vectors including the inserts of WISP1-T1 or WISP1-T2 were transformed in chemically competent One Shot®TOP10 cells, while the WISP2 containing vector was transformed into One Shot®Stbl3 cells. PCR®2.1-TOPO®vectors are ampicillin resistant, thus it was necessary to prepare LB/ampicillin agar plates prior to transformation. The cells were stored at -80°C and immediately defrosted before the transformation procedure started. 2μl of each TOPO®reaction was added to 50μl cells and incubated for 30min on ice. Cells were shortly warmed up by 42°C for 30sec and immediately cooled down on ice for 2-3min. 250μl outgrowth SOC medium (preheated) was added to the vials and cells shook 1h at 37°C. During the incubation, LB/ampicillin agar plates were preheated and 40μl of a 40mg/ml X-gal stock solution (necessary for blue/white screening) was dispensed onto two of these plates. After 1h, 200μl/vial were plated onto LB/ampicillin agar plates. One Shot®TOP10 cells were plated on X-gal covered agar plates, while One Shot®Stbl3 cells are not convenient for blue/white screening and were plated on pure LB/ampicillin agar plates.

Blue/white screening

Additional to the clone selection via ampicillin resistance of the TOPO®vector, One Shot®-TOP10 cells are convenient for blue/white screening. This is a common method to detect successful ligation of vector based gene cloning. The TOPO®vector encodes a subunit of the LacZ protein (β-galactosidase) with an internal multiple cloning site (MCS). The One Shot®TOP10 cells encode the remaining subunit to form a functional β-galactosidase enzyme. During the TOPO®cloning procedure, the inserts were ligated into the MCS within the lacZ gene. This will disrupt protein expression, thus positive clones will lack functional β-galactosidase. X-gal is a modified galactose sugar that is metabolized by β-galactosidase following the characteristic blue colour in the colonies containing a vector without insert. Colonies without a vector were not able to grow on ampicillin agar plates, while white colonies contained a vector + insert. These colonies weren't able to metabolize X-gal, because they lack functional β-galactosidase.

Minipreperation of plasmid DNA

Agar plates were incubated over night at 37°C. Respective and white coloured clone colonies were picked and cultivated in 2ml LB/amp-medium at 37°C with constant shaking for 12-16h. The medium contained 100mg/ml ampicillin to ensure plasmid propagation. Glycerol stock solutions of each clone in a 3:1 (glycerol/germs) ratio were constituted and stored at -80°C for further experiments. According to the manufacturer's instructions of the NucleoSpin®Plasmid kit (Marcherey & Nagel), 1ml of the saturated E. coli-LB culture was used to isolate the plasmid DNA in a provided buffer system. First, the culture was pelleted via centrifugation (30s at 11.000xg) and subsequently resuspended. Plasmid DNA was separated from the E. coli host cells by a SDS containing alkaline lysis buffer. Neutralization buffer was added to the lysate to creates appropriate conditions for binding of plasmid DNA to the silica membrane of the NucleoSpin®Plasmid binding column. Precipitated protein, genomic DNA, and cell debris were then pelleted by centrifugation and the supernatant was loaded onto the binding column. An additional centrifugation step was necessary for binding plasmid DNA onto the silica membrane. Washing with provided ethanolic buffer removed contaminations like salts, metabolites and soluble macromolecular cellular components. Pure plasmid DNA was finally eluted under low ionic conditions with a slightly alkaline buffer (5mM Tris/HCl, pH 8.5).

Concentration of plasmid DNA was determined by 1:25 dilution of plasmid suspension in HPLC. Absorption was measured at 260nm using UV-light permeable cuvettes. Purity was estimated by the quotients E_{260}/E_{280} and E_{260}/E_{230}, since the absorption of proteins occurs

at 280nm while contaminants like carbohydrates and peptides absorb at 230nm. To exclude contaminants, E_{260}/E_{280} should be 2.0 and E_{260}/E_{230} should be larger than 2.0.

Restriction enzymes were used to cut plasmid DNA at specific sequences to verify successful plasmid preparation. Previously, modified primer pairs enclosed restriction sites for XhoI (forward primer) and EcoRI (reverse primer) flanked the expected open reading frames of the three cDNA clones. These restriction sites were amplified during the proof reading PCR of the open reading frames and cloned into the TOPO®vector. 1U enzyme was used to restrict 1μg plasmid DNA in the appropriate buffer system. The restriction suspension was incubated for 2h at 37°C and subsequently verified using agarose gel electrophoresis. The expected sizes of the WISP1-T1, WISP1-T2 and WISP2 sequences are stated in section 5.11, table 5.11.

Midipreperation of plasmid DNA

Clones containing an insert with the expected size were amplified to achieve higher quantities of plasmid DNA. Using a diluting loop, marginal amounts of the glycerol stocks sufficed to inoculate 50ml LB/ampicillin medium. The suspension was incubated over night with constant shaking at 37°C. Following the manufacturer's instructions of the PureYield®plasmid midi preparation kit (promega), the saturated E. coli-LB culture was pelleted via centrifugation. Subsequently, the pellet was resuspended, lysed and neutralized to ensure appropriate conditions for removing cellular debris. The lysate was added onto the provided PureYield®Clearing Column and centrifugation separated cellular debris and plasmid DNA. An additional centrifugation step was performed for binding the plasmid DNA onto the membrane of the PureYield®Binding Column. Several washing steps, like endotoxin removal wash, removed substantial amounts of protein, RNA and endotoxin contaminants from purified plasmid DNA. 600μl nuclease-free water was added onto the membrane of the binding column to elute purified plasmid DNA. Concentration of plasmid DNA was determined depicted in subsection 6.3.4, page 52. Insert plasmid DNA were verified by sequencing analysis (Subsec. 6.3.3) to ensure a completely correct progression of bases within the open reading frame.

6.3.5. pBacPAK8 Cloning

Vector linearization and restriction of WISP1-T1, -T2 and WISP2 target sequence

The AcMNP virus genome is very large (134kb), thus the small transfer vector pBacPAK8 (<10kb) was used to integrate the target sequences of WISP1-T1, -T2 or WISP2 into the viral genome. 3μg of each target sequence (verified by sequencing analyses) and the transfer vector were restricted seperately with EcoRI and XhoI (1U/μg) over night at 37°C. To obviate recircularization and religation of the linearized vector, 1μl calf intestinal alkaline phosphatase (CIAP) and 5μl dephosphorylation buffer were added to the pBacPAK8 restriction reaction. The enzyme catalysed the 5' phosphate group's removal, thus DNA fragments that lack the 5' phosphoryl termini cannot self-ligate. After incubation for 1h at 37°C each target sequence and the linearized transfer vector were loaded onto a 1% agarose gel with a constant current of 145V for 1h. The visualization of specific DNA fragments took place by exposure to UV-light.

Purification of DNA from TBE-agarose gels

DNA bands of the target sequences were excised with a scalpel and size of the gel slice was minimized by removing excess of agarose. According to the manufacturer's instruction of the NucleoSpin® Extract II kit (purchased from Machery & Nagel), the gel slice was weight and 2 volumes of the dedicated buffer was added to 1 volume gel (e.g. 200μl buffer/100mg gel). The gel was incubated at 50°C for 10min and occasionally vortexed to solubilize the

agarose. Especially binding columns were used to bind DNA fragments onto silica-gel-based membranes during centrifugation (13000xg, 1min). The membrane was washed with desalting buffer and dried by centrifugation (13000xg, 2min). Pre-heated elution buffer was added onto the membrane to dissolve DNA fragments via an additional centrifugation step (13000xg, 1min).

Integration of target sequences into the transfer vector pBacPAK8 with subsequent transformation and plasmid purification

The restriction endonucleases EcoRI and XhoI produced palindromic, sticky ends in the pBacPAK8 vector and the WISP target sequences. Instantaneous after gel extraction, the cohesive ends were ligated according to the manufacturer's instructions of the Fast-Link DNA Ligation Kit (Biozym). The required amount of a 10kb sized vector is 75-150ng and the ratio between vector and insert should be 2:1. The reactions were incubated at RT for 5min and subsequently heated at 70°C (15min) to stop the enzyme activity of the ligase. The pBacPAK8 vectors including the inserts of WISP1-T1, -T2 or WISP2 were transformed in chemically competent One Shot®TOP10 cells. Transformation was performed (Subsec. 6.3.4, page 52) and bacteria suspension was plated on LB/amp-agar plates and incubated at 37°C over night. After plasmid mini preparation, the restriction enzymes EcoRI and XhoI were employed to verify successful ligation, transformation and plasmid preparation. Further restriction and cloning steps were conducted to integrate an additional Fc-tag into the pBacPAK8 vector. This tag has the sequence encoding for the Fc domain of human immunoglobulin protein IgG1 (740bp) and was cloned in frame at the C terminus of the WISP protein sequences. The Fc domain binds well to protein G and purification of Fc tagged fusion proteins were later performed using protein G coupled to sepharose columns (Subsec. 6.3.6, page 55). For cloning the tag in frame behind the WISP sequence into the pBacPAK8 vector, both (vector and Fc-tag) were restricted with EcoRI and NotI in a provided buffer system at 37°C over night. Recircularization and religation of the linearized vector was avoid by dephsophorylation before the reaction was loaded onto a 1% agarose gel. DNA bands were excised with a scalpel and gel extraction, ligation and tranformation were performed described previously. Sequencing analysis approved the correct sequences of WISP1-T1, -T2, WISP2 and the attached Fc-tag within the open reading frames.

6.3.6. Recombinant protein expression and purification

AcMNP virus transfection of SF21 cells

The transfer vector pBacPAK8 and an additional expression vector were cotransfected into SF21 cells. Double recombination between viral sequences in the transfer vector and conformable sequences in the expression vector transferred the target cDNAs of WISP1-T1, -T2 or WISP2 into the viral genome. Cells were cultivated as monolayers in 150cm^2 cell culture flasks with BacPak complete medium. For transfection, SF21 cells were seeded onto 6 well plates at a density of 1x10^6 cells/well and incubated at 27°C for 1.5h. After cells attached at the bottom of the 6 well plates, previous medium was replaced with serum free Grace's basic medium and incubated at RT for 20min. During this incubation, the transfection reagents were prepared according to the manufacturer's instructions of the BacPAK^{TM}Baculovirus Expression System (Tab. 6.5). The kit included the positive control pBacPak8GUS. Recombination between this specific transfer vector and the expression vector generated recombinant viruses that express β-glucuronidase (GUS). GUS expression was later detected by application of X-Gluc, which produced a blue precipitate in the presence of β-glucuronidase.

Reaction tubes were incubated at RT for 15min and medium was removed from the wells. 1.5ml fresh serum free Grace's basic medium was added onto the cells and the Bacfectin-DNA

Table 6.5.: *Standard transfection assay for (r)protein production with the Baculovirus Expression System*

	Experiment 1-3 [μl]	**Positive control [μl]**	**Negative control [μl]**
HPLC water	86	86	91

pBacPak8GUS (100ng/μl)	-	5	-
Expression vector (Bsu36 I digest)	5	5	-
Bacfectin	4	4	4
Final volume	100	100	100

mixture was pipetted dropwise to the medium and incubated for 5h at 27°C. Subsequently, old medium was replaced with Insect Express SF9 medium and X-gluc (300μg/ml) was added to the control dishes.

AcMNP virus amplification in SF21 cells

After 72h at 27°C, blue colour of the positive control was inspected. The medium, containing the produced viruses (P0), was collected six days after transfection and stored at 4°C until the first virus amplification was performed. Using Insect Express SF9 medium, SF21 cells were seeded with a density of 1x10^6 cell/well in a 6 well plate and incubated for 2h at 27°C. Different concentrations of P0 viruses (1:10, 1:100, 1:1000) were added to the cells and incubated at 27°C for virus amplification. After seven days, medium was removed and centrifuged at 1200xg (5min). Supernatants (P1 viruses) were replaced in new caps and stored at 4°C for the second amplification step. Because WISP1-T1, -T2 and WISP2 proteins were secreted into the medium, western blotting analyses with a primary antibody against the Fc-Tag were performed to detect the efficientest P1 virus concentration for the following amplification procedure (Subsec. 6.3.8). After seven days, 5x10^6 SF21 cells were disseminated in 5ml Insect express SF9 medium/25ml cell culture flask and incubated at 27°C for several hours. The P1 virus concentration, which yielded most target protein was diluted 1:25, 1:62.5 and 1:500 and added to the Insect express SF9 medium upon the recently seeded cells. After further seven days, all P2 virus supernatants were collected and western blotting analyses were retried to identify the efficientest P2 virus titer. Finally, 200μl of the efficientest virus supernatant was added into 20ml medium to infect 1,6x10^7 cells, seeded as monolayers in 150cm^2 cell culture flasks. Cells incubated at 27°C for 5-7 days, before protein purification procedures were implemented.

Purification of secreted rWISP proteins

All rWISP proteins were expressed as fusion proteins tagged with an Fc-tag. However, the secreted proteins were purified using 1ml HiTrap Protein G Sepharose columns. Protein G

is a Type III Fc receptor and belongs to the group G cell surface proteins of Streptococci. This receptor binds to the Fc region of IgG and is matrix-bound within the HiTrap Sepharose columns. Cross-reactions with albumin in the medium were avoided, since the native albumin-binding region of protein G was genetically deleted. SF21 cells were able to produce the rWISP proteins four-seven days after transfection. The medium of three major cell culture flasks (150cm^2) was collected and centrifuged 5min by 4500xg. The supernatant, containing the specific (r)protein, was transferred into a new falcon and incubated on ice until the purification procedure started. The equilibration of the HiTrap Protein G Sepharose column was achieved with 10ml PBS. After equilibration, 60ml supernatant was loaded step by step onto the column carefully followed that a maximum of 2ml/min was filtered. Subsequently, the column was washed with 10ml PBS upside down. The strong affinity between protein G and IgG at pH 7.0 was dissolved by decreasing the pH of the elution reagent glycine to pH 2.2. Different protein fractions were collected in eppendorff caps. The first fraction contained 500μl eluate and 20μl Tris (3M, pH 8.0) for neutralization while further fractions consisted of 1ml eluate and 40μl Tris (3M, pH 8.0). The purified protein fractions were adjusted to pH 7.0 and stored at 4°C. The columns were washed with 10ml PBS and charged with 6ml ethanol to prevent desiccation.

6.3.7. Determination of protein concentration

Concentrations of the (r)protein fractions were determined after each purification and prior to each application by the Micro-Bradford method. This assay relies on binding of the dye Coomassie Blue G250 to proteins, based on the method originally described by (Bradford 1976). The dye can exist in three charged forms, the cationic red and green forms (absorbance max. at 470nm and 650nm) and the anionic blue form (absorbance max. at 590nm). Since only the anionic blue form binds to proteins, the quantity can be estimated by determining the amount of blue dye. Since it was necessary to gain a calibration curve before protein measurement took place, different calibration standards with of 25, 50, 75, 100, 150, and 250μg/ml BSA were diluted in 100mM glycine. Thus, a blank of 10μl 100nM glycine and 10μl per standard were vortexed and measured two times. 5x Roti-Quant (contained Coomassie Blue G250) was diluted 1:4 in distilled water and 500μl 1x Roti-Quant was mixed with 10μl (r)protein in a micro cuvette. After 10min at room temperature measurement of absorption was performed at 595nm in a photometer, which calculated absolute protein concentrations according to the obtained calibration curve.

6.3.8. Western blotting

Western blotting (immuno blotting) was used to determine expected size and purity of the rWISP-Fc proteins. Protein samples (250-300ng) were first loaded on a SDS page and separated during gel electrophoresis according to their size. Therefore, proteins were denaturated with SDS (sodium dodecyl sulfate). It dissolves hydrophobic molecules to reduce proteins to their primary structure (linearize) and covers the proteins with uniform negative charge by binding to disulfide linkages of the amino acids. A polyacrylamide gel (polymer of acrylamide monomers) was used to separate different sized proteins by moving at different rates during the application of a direct current. The gel consisted of two compartments (Tab. 6.6). The upper was formed by the stacking gel and yielded lower acrylamide concentration and different pockets, which were needed to accumulate the loaded proteins. The lower compartment (separating gel) consisted more acrylamide to separate different sized proteins by their mass.

It was important to add TEMED and APS immediately before use to the mixture, because they act as radical starters for gelling. One short glass plate and one spacer glass plate were

Table 6.6.: *Standard composition for two SDS-acrylamide gels*

	5% stacking gel [ml]	**12.5% separating gel [ml]**
distilled water	2.40	4.80
Rotiphorese gel 40 (29:1) acryl-amide/bisacrylamide mix	0.50	3.75
stacking gel buffer	1.00	–
separating gel buffer	–	1.25
10% SDS	0.04	0.10
TEMED	0.004	0.004
10% APS	0.04	0.10

clamped into a special fastener, which sealed bottom and lateral rims of the plates. The mixture of the separating gel was added between the glass plates (filling 2|3 of the space) and covered with 2-propanol until polymerization. After 20min, the 2-propanol was removed and the stacking gel mixture was loaded onto the polymerized separating gel. Combs were used to generate pockets into the stacking gel during its polymerization. After additional 20min, both glass plates (including the gel) were fitted into an electrophoresis cell, designed to hold two gels, which was inserted into a buffer tank. Two different buffers were needed to generate an electric field for protein separation. Upper buffer was filled between the gel trays while lower buffer was filled into the buffer tank up to the bottom of the gel trays. Equal amounts of protein were diluted with distilled water to a final volume of 10μl and added to 10μl sample buffer (yielded bromphenol blue). After an additional denaturating step (5min at 70°C), the samples and a rainbow marker were loaded onto the stacking gel and a direct current at a voltage of 190V was applied for about 40min. Migration of the proteins was controlled by location of bromphenol blue. After the separation was finished, two blotting papers and a nitrocellulose membrane were moistened with transfer buffer and placed on the bottom of the blotting chamber. One gel and two further wet blotting paper were placed onto the nitrocellulose membrane. The upper plate electrode was placed on top and a current of 150mA per membrane was applied for 2h. The proteins were transferred onto the nitrocellulose membrane via migration according to their negative charge towards the anode. Subsequently the membrane was incubated in a blocking solution for 2h to reduce non-specific protein interactions between the membrane and antibodies. A primary antibody against the Fc-tag was diluted 1:1000 in a buffer solution (PBS) containing the carrier protein BSA and incubation of the membrane was done over night at 4°C. The membrane was washed 4x 15min in washing solution I, before it was incubated with the anti-rabbit IgG secondary antibody for 1h. Anti rabbit IgG was diluted 1:2000 in PBS/BSA and labelled with the reporter enzyme horseradish peroxidase that allows visual identification by producing fluorescence. After rinsing the membrane 4x 15min in washing solution II, unbound secondary antibody was removed and the membrane was prepared

for detection by using the ECL Plus kit (purchased from Amersham). The kit contains the Lumigen PS-3 acridan substrate, which is converted into acridinium ester intermediated by the horseradish peroxidase activity of the secondary antibody. The resulted emission of light was detected by autoradiography. Every membrane was, according to the manufacturer's instruction, incubated in ECL Plus reagents for several minutes. Subsequently, the solution was removed and the membrane was placed (covered in cling film) in an X-ray film cassette. An autoradiography film was placed onto the membrane in a dark room for 2min to 2h, depending on the estimated exposure time. Detected proteins were visualized as dark bands and the size standard was copied by overlaying on the respective membrane.

6.3.9. Silver staining

In addition, silver staining was used to valid the purity of our (r)protein fractions. This is a highly sensitive method for visualization of separated protein bands on polyacrylamide gels. Therefore, 10-50ng amount of protein suffice for detection. Proteins bind silver ions, which can be reduced under appropriate conditions to build up a visible image made of finely divided silver metal (Chevallet et al. 2006). Following the manufacturer's instruction of the Silver staining kit (purchased from Amersham) the polyacrylamide gels were first fixed 30min in a solution of acetic acid and ethanol (1:3) to get rid of interfering compounds. For an increased sensitivity and contrast of the staining, the gel was slewed for additional 30min in a sensitization solution. Rinsing with distilled water (3x 5min) and incubation in silver nitrate staining solution for 20min (in the dark) was necessary for binding silver ions to the proteins. After quick washing with distilled water (2x 1min), the gel was incubated with developer. It was important to observe the gel during development, because duration to unveil bands varies between 2-10min. Subsequently after visualizing protein bands, the reaction was finished with stop solution for 10min and conserved in a vacuum dryer for at least 2h.

6.4. Reduction of gene expression through shRNA techniques

Gene-silencing includes methods by which the expression of one or more genes is reduced (in vivo or *in vitro*). This could be achieved by either the application of DNA or RNA oligonucleotides with a sequence complementary to a mRNA transcript, or through genetically modifications of the chromosomes. In this study, shRNA constructs, integrated into an expression vector of the lentiviral genome, were used to generate stable siRNA expression against WISP1 in different kind of cell types. A set of five different shRNA constructs against WISP1-T1 and -T2 was commercially supplied from the RNAi Consortium (TRC) of Thermo Fisher Scientific. These constructs were designed to include a 21bp hairpin stem (sense and antisense) flanking a loop of 6bp (Sec. 5.5). Each hairpin sequence was integrated into the lentiviral vector pLKO.1 (HIV-based) and provided as bacterial cultures of E.coli (DH5α) in LB-Lennox medium complemented with 8% glycerol.

Similarly, the TurboGFP^{TM}control vector (based on the TRC2-pLKO-puro vector) was used as a positive control for measuring transfection and transduction efficiency. After expression, GFP exhibits bright green fluorescence when exposed to blue light and therefore indicates successful virus infection of the target cells. The empty TRC2-pLKO-puro vector was used as a negative control. This pure vector control contains no shRNA insert and thus will not activate the RNAi pathway. The second negative control was a non-targeting shRNA vector (scrambled control). It contains a short hairpin sequence of 21bp (sense and antisense) flanking a loop of 6bp with mismatches to any known human gene (Sec. 5.5). Therefore, it activates RISC and the RNAi pathway, but doesn't affect the expression of any human gene. This

control allowed the examination of the effects of shRNA transduction and RNAi activation on the gene expression. Both negative controls were useful for observation of cellular effects of the transfection process. It was similarly necessary to generate envelope (pMD2.G) and packaging (psPAX2) plasmids with the consecutively described procedures. Cotransfection of either shRNA or control plasmids additional to envelope and packaging plasmids were required to generate efficient virus particles.

6.4.1. Amplification of shRNA and control constructs

The provided glycerol stock solutions were stored at -80°C. Using a dilution loop, marginal amounts were removed and plated on LB/ampicillin agar plates. After nearly 16h at 37°C, single colonies were picked and cultivated in 2.5ml LB/ampicillin medium at 37°C with constant shaking for 12-16h. Following plasmid mini preparation (Subsec. 6.3.4, page 52), positive clones were identified using restriction endonucleases. 1U enzyme was used to restrict 1μg plasmid DNA in the appropriate buffer system and restriction suspension was incubated for 1h at 37°C. Successful insertion of the shRNA construct into the MCS of the pLKO.1 vector, enabled double restriction with EcoRI and NcoI. Gel electrophoresis visualized two bands (∼2kb and ∼5kb) for plasmid DNA including the shRNA construct and only a linearized vector band (∼7kb) in shRNA negative plasmids. Positive samples were verified using sequencing analysis (subsection 6.3.3), amplified through transformation in chem. competent E.coli cells (Subsec. 6.3.4, page 52) and subsequent purified with plasmid midi preparation procedures (Subsec. 6.3.4, page 53).

6.4.2. Lentiviral transfection of HEK-293T cells

Approximately 24h prior to transfection, HEK-293T cells were seeded onto 6 well tissue culture plates at a density of 6x10^5 cells/well in 3ml DMEM Ham's F12 medium with L-glutamine and 10% FCS (without antibiotics). Cells were incubated over night at 37°C in a humidified atmosphere enriched with 5% CO_2 and transfected immediately after they reached a confluence of 60-80% (Tab. 6.7).

Subsequently, DMEM Ham's F12 medium was added to a final volume of 80μl per standard transfection assay. Lipofectamine™2000 treatment was used to alter the plasma membrane, which allows plasmids to enter the cytoplasm. Therefore, a lipofectamine master mix was prepared, containing 10μl lipofectamine and 90μl DMEM Ham's F12 medium for each reaction. Following an incubation of 5min at RT, 100μl lipofectamine mix was added to each reaction tube and incubated for 20min at RT. Afterwards, a total reaction volume of 180μl was pipetted dropwise into the medium of the seeded HEK-293T cells and incubated for nearly 18h at 37°C with 5% CO_2. All following procedures were accomplished according to the guidelines of the local S2 ethic commission of the University of Würzburg. After nearly 18h, used medium was removed from the HEK-293T cells and replaced with 5ml fresh DMEM Ham's F12 medium containing 30% FCS and 1% Pen/Strep. The GFP positive control was inspected under exposure to UV-light. It has a major excitation at a wavelength of 395nm, a minor one at 475nm and the emission peak is at 509nm, which is in the lower green portion of the visible spectrum.

6.4.3. Lentiviral transduction of target cells

Target cells were seeded in adequate plating densities, depending on cell type and culture vessel size (Tab. 6.8) in the provided medium (Subsec. 5.12.5, Tab. 5.18).

Target cells (except Tc28a2, C28I2) and transfected HEK-293T cells were incubated at 37°C (Tc28a2, C28I2 at 32°C) for further 24h. Transduction of the target cells took place on the

Table 6.7.: *Standard transfection assay for virus assembling for gene expression studies through shRNA constructs*

	shRNA construct [μg]	**Negative scrambled control [μg]**	**Negative pure vector control [μg]**	**Positive GFP control [μg]**

Tc28a2	25cm^2 flask	2.0x10^5

third day after HEK-293T cells were transfected. Therefore, total medium (5ml/sample) was removed from the HEK-293T cells and centrifuged at 4500xg for 5min to dissociate cell debris and virus supernatant. Subsequently, used medium was removed from the target cells and replaced with adequate amount of virus supernatant. Polybrene (8μg/ml) was added dropwise to the virus supernatant onto the target cells. This hexadimethrine bromide polymer was used to increase the efficiency of infection by neutralizing the charge repulsion between virions and sialic acid on the cell surface. Following, cells were incubated at 37°C (Tc28a2, C28I2 at 32°C) and used medium was replaced with fresh medium one day after transduction and additional every second day.

6.4.4. Isolation of cellular RNA

RNA isolation of WISP1 down-regulated and control cells took place simultaneously at several days to investigate the gradient of WISP1 gene-silencing. Total RNA from cultured cells was isolated following the manufacturer's instruction of the NucleoSpin®RNA II kit (Macherey-Nagel GmbH). Cells were disrupted and homogenized with a guanidine isothiocyanate- and β-mercaptoethanol-containing lysis buffer that inactivates RNases. Samples were loaded onto a filtration column to reduce viscosity by centrifugation. Subsequently, equal volumes of 70% ethanol was added to the filtrated lysate, to generate conditions that promote selective binding of RNA to a NucleoSpin column membrane. Especially binding columns were used to bind RNA to silica-gel-based membranes during centrifugation (8000xg, 30sec). The silica membrane was treated with membrane desalting buffer, to ensure appropriate conditions for the endonuclease DNase I. Since no RNA purification procedure removes 100% of the DNA, it is suitable to use DNase I for eliminating remaining DNA. Contaminants were washed out by appropriate buffers and purified RNA was eluted with 30μl HPLC by centrifugation (11000xg, 60sec). Samples were stored at -80°C. Concentration of mRNA specimens was determined by 1:25 dilution of RNA suspension in HPLC. RNA absorption was measured at 260nm using UV-light permeable cuvettes. The extinction of 1 E_{260} was conformed to 40μg/ml RNA. Purity was estimated by the quotients E_{260}/E_{280} and E_{260}/E_{230}, since the absorption of proteins occurs at 280nm while contaminants like carbohydrates and peptides absorb at 230nm. To exclude contaminants, E_{260}/E_{280} should be 2.0 and E_{260}/E_{230} should be larger than 2.0.

6.4.5. Reverse transcriptase polymerase chain reaction (RT-PCR)

Because mRNA is less stable than DNA, it is conventional to use cDNA to investigate gene expression patterns of specific genes in cells and tissues. cDNA is a single- or double strained DNA that is complementary to a certain sequence of mRNA.

After RNA isolation, cDNA was synthesized during reverse transcription, using the Bioscript reverse transcriptase (polymerase) purchased from Bioline. The cDNA synthesis was performed according to the manufacturer's instructions. Therefore, identical amounts of total RNA (1-2μg) were first incubated with random hexamer primers at 70°C to denaturate RNA secondary structures. Subsequently, the samples were chilled on ice were the random hexamers annealed to the RNA template. RNase inhibitor, dNTPs, reverse transcriptase and the corresponding buffer were added and the reactions extended at 25°C for 10min before the elongation starts at 42°C (1h). Enzyme inactivation at 70°C was necessary to stop the reaction. HPLC water diluted the samples to a final volume of 50μl. Subsequent semi-quantitative PCR analysis enabled the detection of specific gene expressions. Table 6.9 reflects a standard protocol and the corresponding reaction steps accommodated for the PTC-200 Peltier thermal cycler. Therefore, gene specific primers were used to anneal in the cDNA sequence of the gene of interest. This enabled the Taq DNA polymerase to elongate the sequences to double

stranded PCR products specific for the elected gene. MangoTaq™ DNA polymerase was used according to the manufacturers instruction with the respective, provided buffer system.

Steps 2-4 were repeated 22-39 times depending on the results of the following gel electrophoresis procedure. Modified assays, with higher amounts of $MgCl_2$ and/or by addition of DMSO, were performed as stated in section 5.11, table 5.11. PCR primers were either already established in the laboratory or designed using Primer3 software (Rozen and Skaletsky 2000). To exclude false positive detection of DNA contaminants, primer pairs were preferably selected, which anneal in DNA sequences of different exons (intron-spanning). PCR reaction conditions, like annealing temperature, cycle number and $MgCl_2$ and/or DMSO concentration were first optimized and subsequent sequencing analysis of the respective PCR product assessed gene specificity of each primer pair (Subsec. 6.3.3).

6.5. cDNA microarray

cDNA microarrays are small, solid supports onto which the sequences from thousands of different genes are attached at fixed locations. A microarray works by exploiting the ability of a given mRNA molecule to bind specifically to the DNA template from which it originated. Comparison of separate chips, loaded with different RNA specimens, enables the estimation of specific gene expression profiles. To investigate differences in the expression patterns of WISP1 depleted and control cells, knock-down experiments were performed in hMSCs (n=3) and the chondrocyte cell line Tc28a2 (n=5). In both cell types total RNA of WISP1 down-regulated and scrambled control cells was isolated on day six after transfection. The present down-regulation of WISP1 and a successful RNA isolation were verified by RT-PCR and gel electrophoresis.

6.5.1. Affymetrix GeneChip hybridization

Affymetrix GeneChip hybridization, staining, and scanning of the chips were performed by PD Dr. L. Klein-Hitpass at the Institute of Cell Biology, University of Duisburg-Essen, Germany. Therefore, the different mRNA samples were used to generate biotin-labelled, single-stranded cRNA samples, which were fragmented and hybridized onto the GeneChip Human Genome-U133+2.0 for 16h. The arrays were washed and stained according to the manufacturer's recommendation and finally scanned in a GeneChip scanner 3000 (Affymetrix). Thereby, the staining of hybridized cRNA by streptavidin phycoerythrin conjugate results in emission of light at 570nm, that is proportional to the bound cRNA. The software assigned the light emission to the respective probe sets and computed their intensities.

Microarray Analyses with the statistical software R

All further analyses were performed with the statistical software R (R Development Core Team 2010) and its additional component for microarray analyses, namely Bioconductor (Gentleman et al. 2004b). To analyse the Affymetrix GeneChips, we used the analysis add-on package Affy (Gautier et al. 2004). Raw data was visually quality controlled by looking for defective or inadequately spotted regions of the chip itself. Further, RNA degradation plots were used to determine the quality of all samples. All samples passed these controls and were used for further analyses. The raw data was normalised using the function expresso of the affy package. All of the three following normalisation steps were applied for each of the experiments: (1) Normalisation using quantiles (Q) without background correction, (2) using the robust multi-array average expression measure (RMA) with background correction and (3) variance

Table 6.9.: *Standard reaction steps: RT-PCR*

stabilization and normalization (VSN) with background correction using the package vsn (Huber et al. 2002). Methods included the pmonly correction and medianpolish options. However, only the method that yielded the best normalisation was used in the following analytical steps, which was determined by comparison of density plots. Linear models for microarray data were fit to expression data using the package limma (Smyth 2005). Empirical Bayes shrinkage was applied to compute moderated t-statistics, moderated F-statistic, and log-odds of differential expression. By these statistics, the AFFX cut-off filter was used to reduce the data to the most significantly differentially expressed probe sets (package genefilter, Gentleman et al. 2012). As on-chip AFFX probe sets are not expected to be significantly differentially expressed, their lowest p-value states a good cut-off point for significance and was used to filter out normal gene probe sets with a p-value above this threshold. A summary of definite parameters disposed during microarray analyses are stated in (Tab. 6.10).

For all remaining probe sets, annotation information was regarded (packages annotate and hgu133plus2.db, Carlson et al. 2012a; Gentleman 2012) and further gene ontologies (GO, package GOstats, Falcon and Gentleman 2007a) and KEGG (package KEGG.db, Carlson et al. 2012b) pathway classifications. We performed GO enrichment for cellular compounds (CC), molecular function (MF) and biological processes (BP) as well as KEGG enrichment analyses

with a hyper-geometric distribution to detect over- and under-represented GO and KEGG terms. Colour-coded heat maps that include significant probe sets of interesting pathways or functional groups of genes were plotted using the package gplots. We further displayed protein interaction networks within pathways to relate expression information to signalling cascades.

6.6. Application of (r)proteins onto target cells

To assess the effects of rWISP1 proteins, both transcript variants were added separately and combined with concentrations of 500ng to WISP1 down-regulated Tc28a2 chondrocytes. For this investigation, cells were seeded as monolayers in 6 well plates with a density of $1x10^5$ cells/well in 3ml hMSC culture medium. WISP1 gene-silencing procedures were performed described previously. Treatment with rWISP1-T1 and/or rWISP1-T2 took place a few hours after the virus transduction occurred and was repeated with every medium change until RNA isolation took place. Scrambled, GFP and pure vector transduced assays served as controls for the examination of differences in the endogenous WISP1 expression after (r)protein treatment. Protein treatment with rWISP2 was similarly performed with a protein concentration of 500ng. Therefore, Tc28a2 chondrocytes were first seeded with a plating density of $2x10^5$ cells/well in 6 well plates. Cells were incubated under normal cell culture conditions at 37°C until they reached 90-100% confluence. Prior to the protein treatment cells were cultivated with serum less medium (0%FCS) for 24h at 32°C and subsequently treated with 500ng rWISP2 for additional 24h. Following RNA isolation and RT-PCR analyses were performed to examine differential expression of endogenous WISP1-T1, -T2 and WISP2 with the corresponding control cells.

6.7. Immunocytochemistry

Apoptosis detection via Fluorochrome Inhibitor of Caspases (FLICA)

Apoptosis, or programmed cell death, is controlled by active cysteinyl aspartate-specific proteinases (caspases). Caspase enzymes are important mediators of apoptotic signals by cleaving a multitude of substrates, which consequently cause cellular demolition (Green and Reed 1998; Nuñez et al. 1998; Thornberry 1999). Methodology of FLICA is based on several cell permeable caspase inhibitors, which bind covalently to the sites of the corresponding active caspase. For visualization, inhibitors are fluorescence-labelled and staining procedures within this thesis were performed with the poly caspase inhibitor VAD-FMK labelled with sulforhodamine (SR). VAD is an amino acid sequence targeting by all caspases, exhibiting red fluorescence through the labelling with SR. The red signal is a direct measure for the number of active caspases, since unbound FLICA diffuses out of the cell and could be washed away. Hoechst, a cell permeable fluorescence marker, was additional used to counter stain nuclei of all cells (apoptotic and viable). Prior to staining procedures, hMSCs were seeded on glass cover slips in 24 well plates with a density of $4x10^4$ cells/well. Approximately 4h later cells were adherent and quiescent for apoptosis induction via zolendronic acid. Cells were treated with 100μM zolendronic acid between 48h and 72h and subsequent staining procedure were performed. For this purpose, staining protocols were observed according to the manufacturer's instructions concerning adherent cells. Thus, FLICA reagent was added at a 1:30 ratio in fresh medium onto the cells for 1h at 37°C. After incubation, medium was removed, 1.5μl Hoechst stain was added into 300μl fresh medium and mixture was used for the next cell incubation (5min at 37°C). Subsequently, cells were washed twice with washing solution and covered, facing down, with a slide containing one drop washing solution. Analysis was performed with fluorescence microscopy using a bandpass filter with excitation 55nm and emission >580nm to visualize red

fluorescence signals of active caspases.

Protein detection

Proteins, like cytochrome c and p53, can be visualized by immuno-cytochemistry labelling methods to infer their location within a cell. Therefor, protein specific primary antibodies were used to detect distinct proteins. Application of a second, fluorescence-labelled antibody against the primary one, was necessary for protein visualization via fluorescence microscopy. Staining procedure was performed according to the manufacturer's instructions for the corresponding specific antibodies. For this purpose, hMSC were seeded on glass cover slips in 24 well plates with a density of $4x10^5$ cells/well. Prior to the staining of specific proteins, cells could be stained with a counterstain (MitoTracker®Red) to visualize cellular mitochondrions. 100nM MitoTracker® Red was added onto the living cells for approximately 30min at 37°C. Subsequently, medium was removed and cells were twice washed with PBS to remove unbound counterstain. Cells were fixed with 4% PFA (paraformaldehyde) for additional 10min and following washed three times with PBS for 5min. It was necessary to permeabilize the cells with 0.1%Tween/PBS for 15min to enable cell entering of the specific antibodies. Possible unspecific binding sites within the cells were blocked with 2% BSA/PBS for 30min at RT. Incubation with the primary antibody (1:100 in 0.5% BSA/PBS for the mouse anti cytochrome c antibody and the rabbit FL393 antibody against p53) occurred at 4°C over night. Next day, antibody solution was removed and cells were washed three times for 5min at RT. Incubation with the secondary antibody (Cytochrome c: rabbit anti mouse IgG/FITC - F0261 1:100 in PBS; p53: goat anti rabbit IgG/FITC - sc2010 1:200 in PBS) was performed for a minimum of 1h at RT. Cells were covered face down with one drop of mounting medium onto a slide. To counterstain concurrently cellular nuclei, 4',6-Diamidino-2-phenylindole (DAPI) was integrated into the mounting medium. Cells were analysed immediately with fluorescence microscopy.

Part III.

Results

CHAPTER
SEVEN

RESULTS

Studies of this thesis comprised the investigation of molecular backgrounds concerning consequences of WISP1 and -2 signalling in primary cells (hMSCs) and different cell lines connected to the musculoskeletal system. The first experiments included the inspection of full-length WISP1 and WISP2 expression in different cell types of the musculoskeletal system to identify these cells as WISP target cells. Since a truncated isoform of WISP1, transcript variant 2 (-T2), has been identified by Yanagita et al. (2007) in non-transformed chondrocytes, primer pairs were designed to detect both variants separately. Depending on the presence of expression patterns, several experiments were designed to investigate WISP-signalling in detail. Figure 7.1 illustrates the workflow of experiments, starting with gene-silencing of a given WISP expression and subsequent microarray approaches in different cell types, over (r)protein production of WISP1-T1, WISP1-T2 and WISP2 up to (r)protein treatment of previously WISP down-regulated target cells.

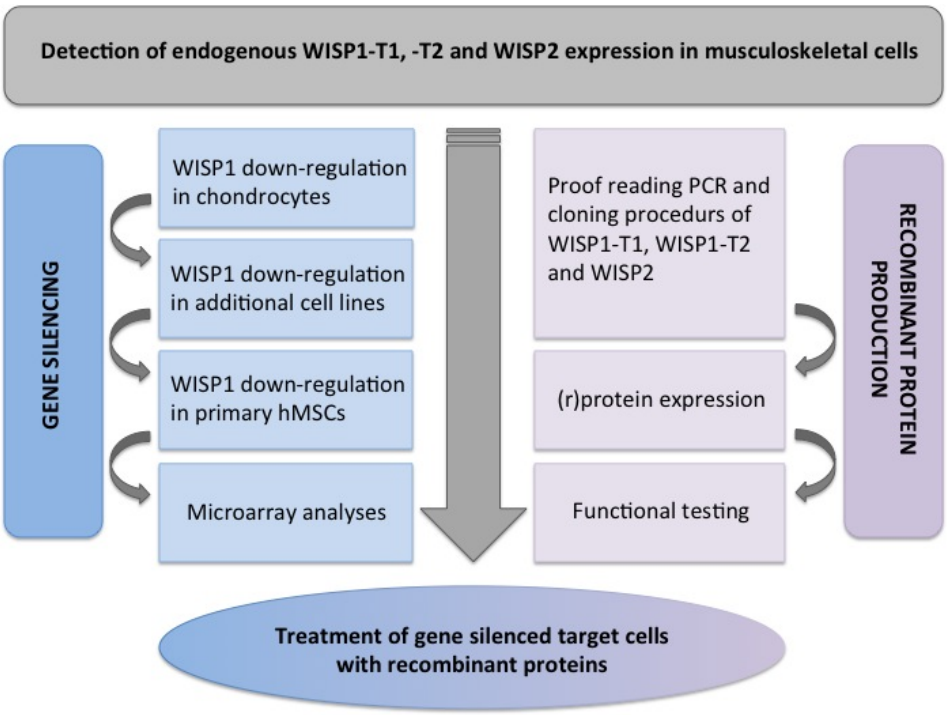

Figure 7.1.: *Schematic illustration of successional experiments.*

CHAPTER
EIGHT

WISP EXPRESSION PATTERNS

The expression of different WISP proteins was achieved by cultivation of monolayer cultures in different cell lines and primary hMSCs. Two different chondrocyte cell lines (Tc28a2; C28I2), three osteosarcoma cell lines (TE-85; MG-63; U2) the human foetal osteoblast cell line hFOB and 12 different hMSC donors were cultivated to investigate the endogenous amount of three different WISP proteins. Total RNA was isolated after cells reached confluence of 90-100%. RT-PCR analyses for both transcript variants of WISP1 showed a continuous expression in all appropriate hMSC donors (Fig. 8.1, A). High expression of WISP2 was only detectable in two different donors (MSC283; MSC354), whereas three different donors (MSC280; MSC486; MSC512) showed only a slight expression (Fig. 8.1, A). All remaining donors reflected no expression of WISP2 at all. A continuous WISP1-T1 expression was also detectable in the osteosarcoma cell lines MG-63 and U2 as well as in the osteoblast cell line hFOB and both chondrocyte cell lines (Fig. 8.1, B-C). Only the third osteosarcoma cell line TE-85 showed no expression of full-length WISP1. Similar expression patterns were detectable in the case of WISP1-T2 (Fig. 8.1, B-C). Except C28I2, which showed slight WISP1-T2 expression, all remaining cell lines expressed high amounts of the second transcript variant. By contrast, no expression of WISP2 was detectable in all examined cell lines. The mRNA levels of the housekeeping gene EF1α was used as an internal control.

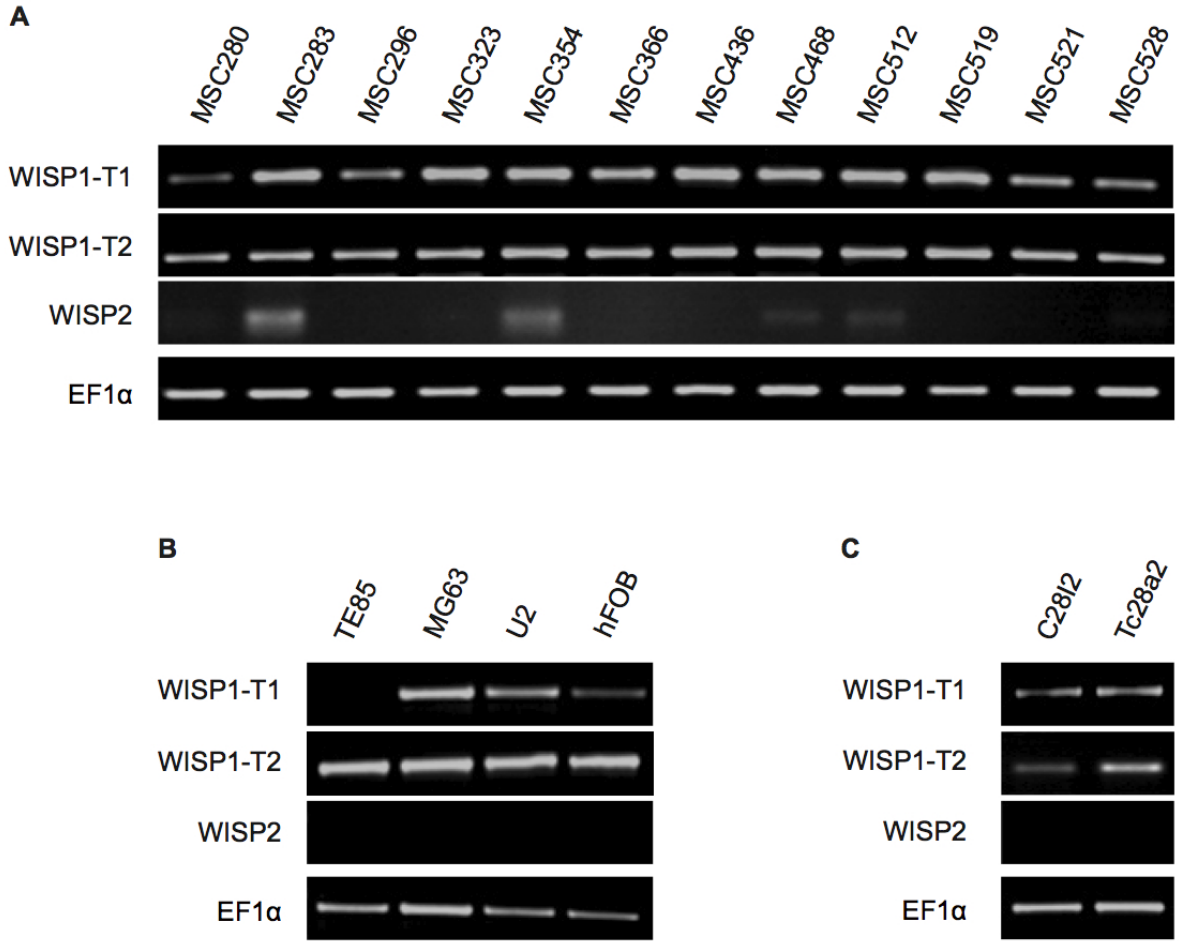

Figure 8.1.: *RT-PCR analysis of WISP expression in hMSCs and different cell lines. (A) constant expression of WISP1-T1 (row 1) and -T2 (row 2) among 12 different hMSC donors. WISP2, in contrast, was only in four of 12 different donors detectable. (B) expression of WISP1-T1/-T2 and WISP2 in three osteosarcoma cell lines (TE85; MG63; U2) and the osteoblast cell line hFOB. WISP1-T1 mRNA was detectable in MG63 and U2 cells as well as in the osteoblast cell line. Expression of the second transcript variant of WISP1 was detectable in all corresponding cell lines, whereas the mRNA of WISP2 could not be found in either of these cell lines. (C) Both transcript variants of WISP1 were expressed in C28I2 and Tc28a2 chondrocytes, while no expression of WISP2 was detectable.*

CHAPTER
NINE

WISP1 GENE-SILENCING

Depending on the presence of expression patterns in the previously described experiments, main focus of the subsequent experiments is dedicated to the functional dissection of WISP1-T1 and -T2. Therefore, gene-silencing studies were performed to examine the influence of WISP1-signalling in several cell types.

9.1. HEK-293T cell transfection and transduction of target cells

Successful gene-silencing of WISP1 by lentiviral transfection was confirmed with a cloning set of five different shRNA constructs. The constructs, integrated into the lentiviral pLKO.1 vector, as well as a GFP control vector, a non-targeting shRNA vector control (scrambled) and a pure vector control were used to transfect HEK-293T cells. Two days after transfection the cell supernatant, containing the recombinant lentiviral vectors, was used to transduce different target cells. The GFP control serves as a positive control for measuring transfection and transduction efficiency. After expression, GFP exhibits bright green fluorescence when exposed to UV-light (Fig. 9.1).

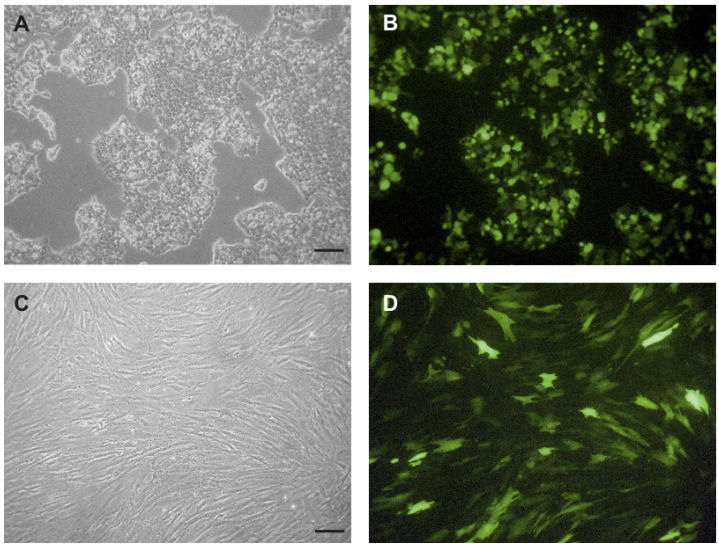

Figure 9.1.: *Lentiviral transfection of HEK-293T cells and transduction of hMSCs. (A) GFP transfected HEK-293T cells 48h after transfection. (B) Visualizing of transfection efficiency by exposure to UV-light. (C) GFP control five days after transduction and (D) equal section of the GFP control under exposure to UV-light. Scale bar=*$100\mu m$.

9.2. WISP1 gene-silencing in Tc28a2 chondrocytes

Virus supernatant, generated via HEK-293T cell transfection, was used to transduce monolayer cultures of different cell lines and primary hMSCs. First, the effectiveness of all five shRNA constructs was monitored by transducing the chondrocyte cell line Tc28a2. Concurrently, GFP and scrambled controls were transduced to discover transduction efficiency, morphological effects and differences in the endogenous amount of WISP1 mRNA. Total RNA was isolated five days after transduction and verified by RT-PCR analyses.

Figure 9.2 illustrates the mRNA level of both WISP1 transcript variants after their down-regulation compared to control cells (scrambled and GFP). A Specific primer pair was selected to detect both variants, thus the first row reflects the mRNA levels of WISP1-T1 and -T2 combined. Only four of five different shRNA constructs and both controls yielded enough mRNA to perform subsequent reverse transcription. Two constructs, shRNA2 and -5, reduced the endogenous amount remarkably, while shRNA1 and -4 transduction resulted in no or little reduction of the WISP1 mRNA. Scrambled and GFP controls revealed no down-regulation of the WISP1 mRNA level in this chondrocyte cell line. In all subsequent experiments, either shRNA2 and/or -5 were used to detect the mRNA levels of WISP1-T1 and -T2.

To clarify the date of an effective WISP1 down-regulation, total mRNA was isolated on day 1 to day 8 (d1-d8) after lentiviral transduction. Subsequently, reverse transcription and RT-PCR analyses were performed to validate the successful down-regulation of both transcript variants (Fig. 9.3). Therefore, the upper row illustrates the amount of WISP1-T1 mRNA in shRNA2 transduced cells, compared to the amount in the scrambled and GFP transduced control cells. Similarly, the second row reflects mRNA amounts of WISP1-T2 in shRNA2 transduced samples as well as in the corresponding control assays. The fourth day (d4) after transduction indicates the first day, with a detectable reduction of the WISP1-T1 mRNA. The successional days display a further decline in the endogenous amount of transcript variant T1. A similar outcome was detectable for the second transcript variant. Starting with the fourth day, the mRNA level was continuously reduced until the last day of the time series (d8). Both controls reflect a consistent expression of either transcript variant during the whole experiment.

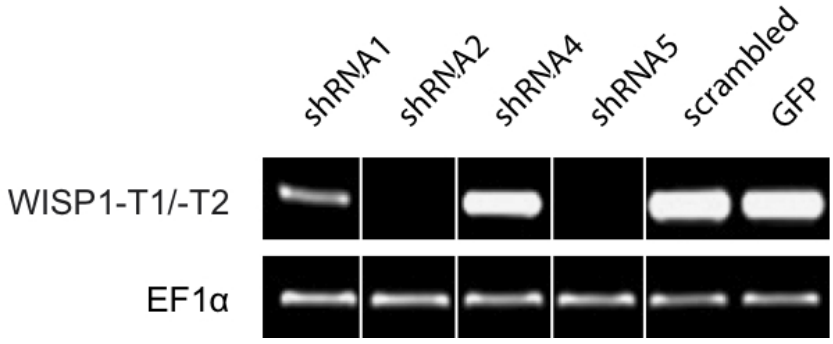

Figure 9.2.: *Range of function concerning four different shRNA constructs against WISP1. Total RNA was isolated five days after transduction. Two constructs, shRNA2 and -5 reduced the endogenous amount of WISP1 remarkably, while shRNA1 and -4 showed only slightly or no effects compared to the scrambled and GFP controls.*

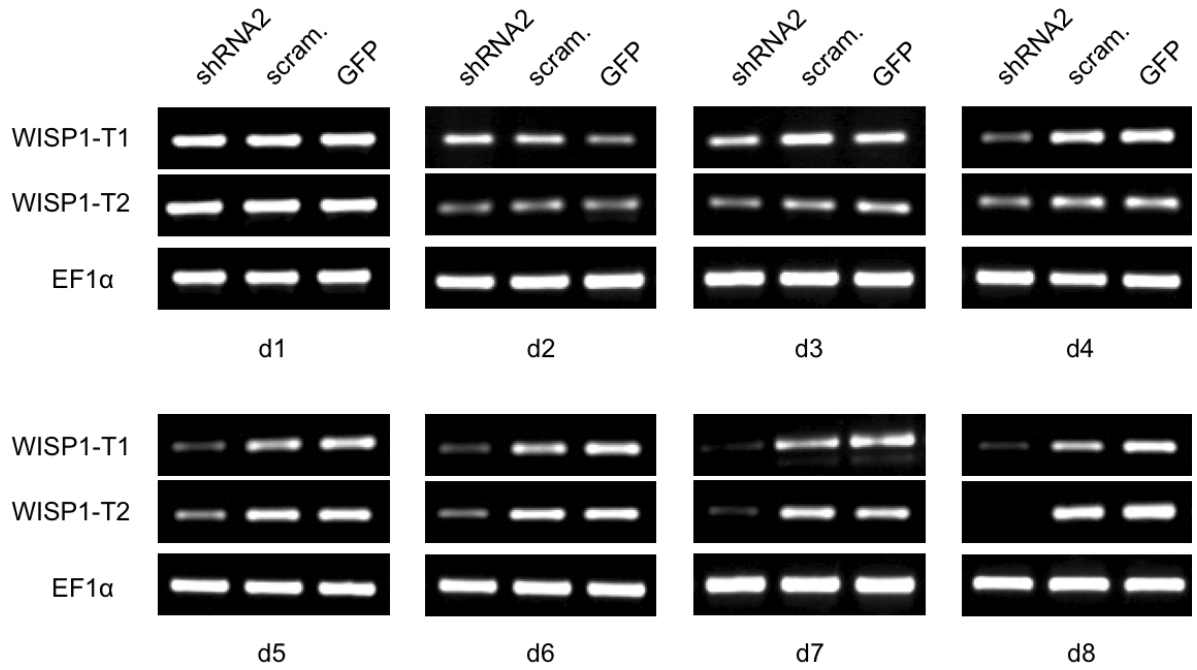

Figure 9.3.: *RT-PCR analysis of Tc28a2 chondrocytes on d1-d8 during WISP1 down-regulation. Total mRNA of shRNA2 transduced samples and two control samples (scrambled, GFP) were isolated on every day for one week. The shRNA2 construct reduced the endogenous amounts of WISP1-T1 and -T2 from the fourth day on, while both control samples showed no effects in the reduction of the WISP1 mRNA levels. Levels of EF1α mRNA were used as internal controls.*

9.3. WISP1 gene-silencing results in cell death in Tc28a2 chondrocytes

In addition to the reduction of the endogenous amounts of both transcript variants, optical differences were observable in WISP1 deficient chondrocytes compared to the control samples. Figure 9.4 reflects these optical differences in chondrocytes in a time series, initiated on the first day after lentiviral transduction. The time dependent optical differences between WISP1 deficient (shRNA2) and sufficient cells (scrambled; GFP) are visible in row 1 to 8. Cell death or proliferating effects within each sample could be observed in column 1-3 for each day of one week. Day 1, 2 and -3 after transduction, revealed no differences between shRNA2 (A1-A3) and scrambled control samples (B1-B3). Considering illustration A4, cell characteristics of shRNA2 transduced samples started to differ on the fourth day after transduction in comparison to the scrambled control samples (B4). Day 5 to 8 intensified these characteristics and chondrocytes containing shRNA2 constructs (A5-A8) showed remarkable differences combined with cell detachment in contrast to the control samples (B5-B8). Under UV-light exposure, sporadic cells slightly indicated GFP expression with green fluorescence on the third day (C3). Furthermore, cells intensified this illumination by GFP expression until the last day of the time series (C4-C8).

Cell death of WISP1 down-regulated chondrocytes was confirmed by transduction of the cells with a second functional shRNA construct (shRNA5). Further, a pure vector control was applied to clarify the optical differences between WISP1 down-regulated samples and their corresponding controls. All assays comprised the same conditions including medium, incubation and handling. Figure 9.5 illustrates Tc28a2 cells eight days after transduction. There were only slight differences observable comparing shRNA2 (A) and shRNA5 (B) transduced cells.

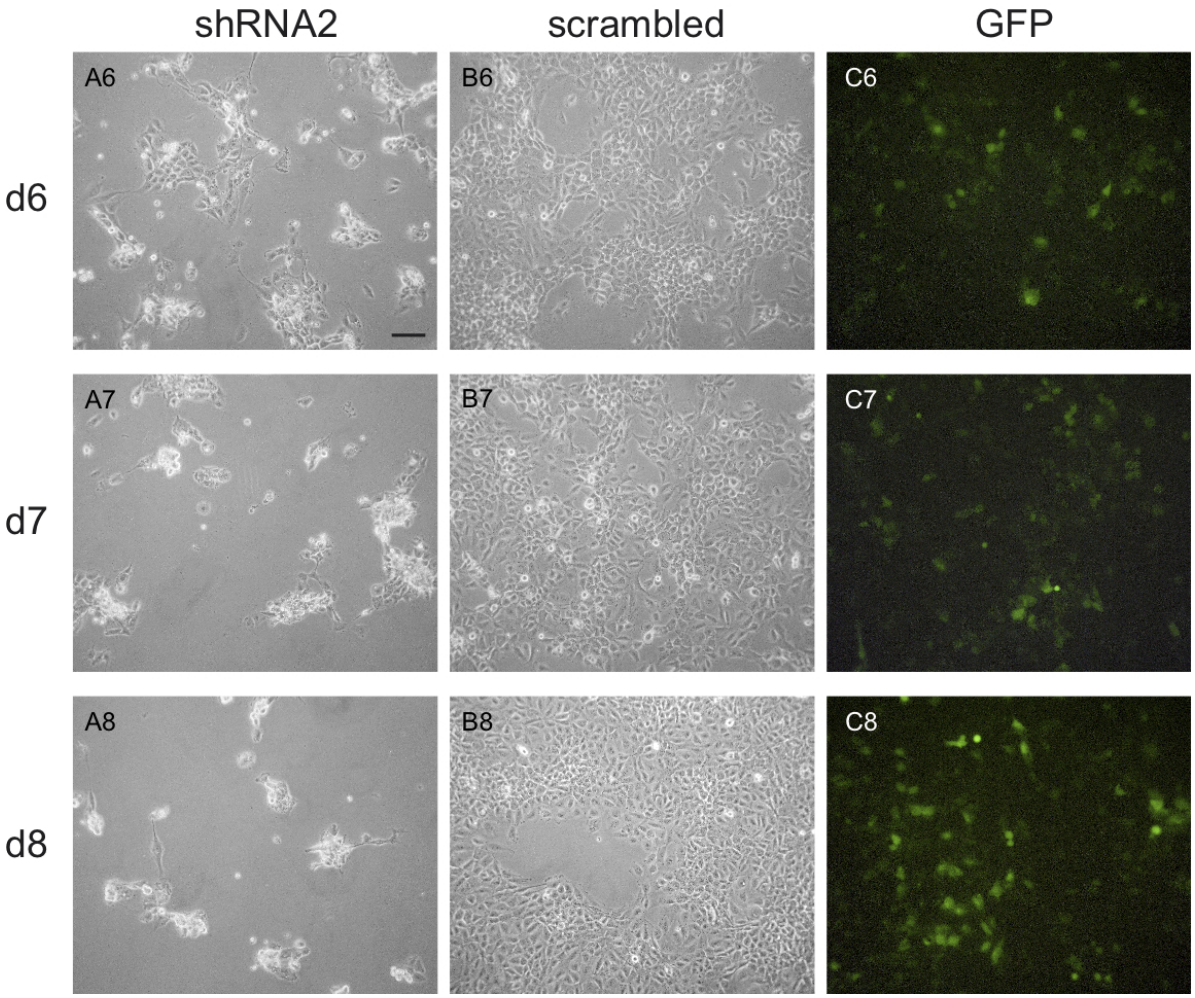

Figure 9.4.: *Cell death of WISP1 deficient Tc28a2 chondrocytes. Column 1 (A1-A6) showed, that WISP1 deficient cells died within one week after the transduction was performed. Day 1 to day 4 displayed a comparable proliferation of shRNA2-transduced cells (A1-A4) and the scrambled control sample (B1-B4). Day five is the first day that indicates optical differences between knock-down (A5) and scrambled control cells (B5). Day 6, 7 and 8 intensified these disparities remarkably (A6-A8, B6-B8). GFP expression was detectable under exposure to UV-light from the third day on (C3-C8). Scale bar=*$100\mu m$

However, in contrast to the scrambled- (C), pure vector- (D) and GFP control (E) both shRNA constructs manifested remarkably optical differences. Cells weren't able to survive in shRNA2 and -5 treated samples, while the three control samples reflected an expected proliferation. GFP expression was verified under exposure to UV-light (F). Total RNA of each sample was isolated on day 8 after transduction and RT-PCR analyses were performed immediately (G). Both shRNA constructs revealed an emersed reduction in the mRNA level of WISP1-T1 and -T2 compared to the control samples (scrambled, GFP and pure vector). Similar experiments, transduced with shRNA2-, scrambled- and GFP plasmids were repeated (n=7) and analysed by RT-PCR and densitometric analysis of the gel bands (Sec. 11.4, Fig. 11.3).

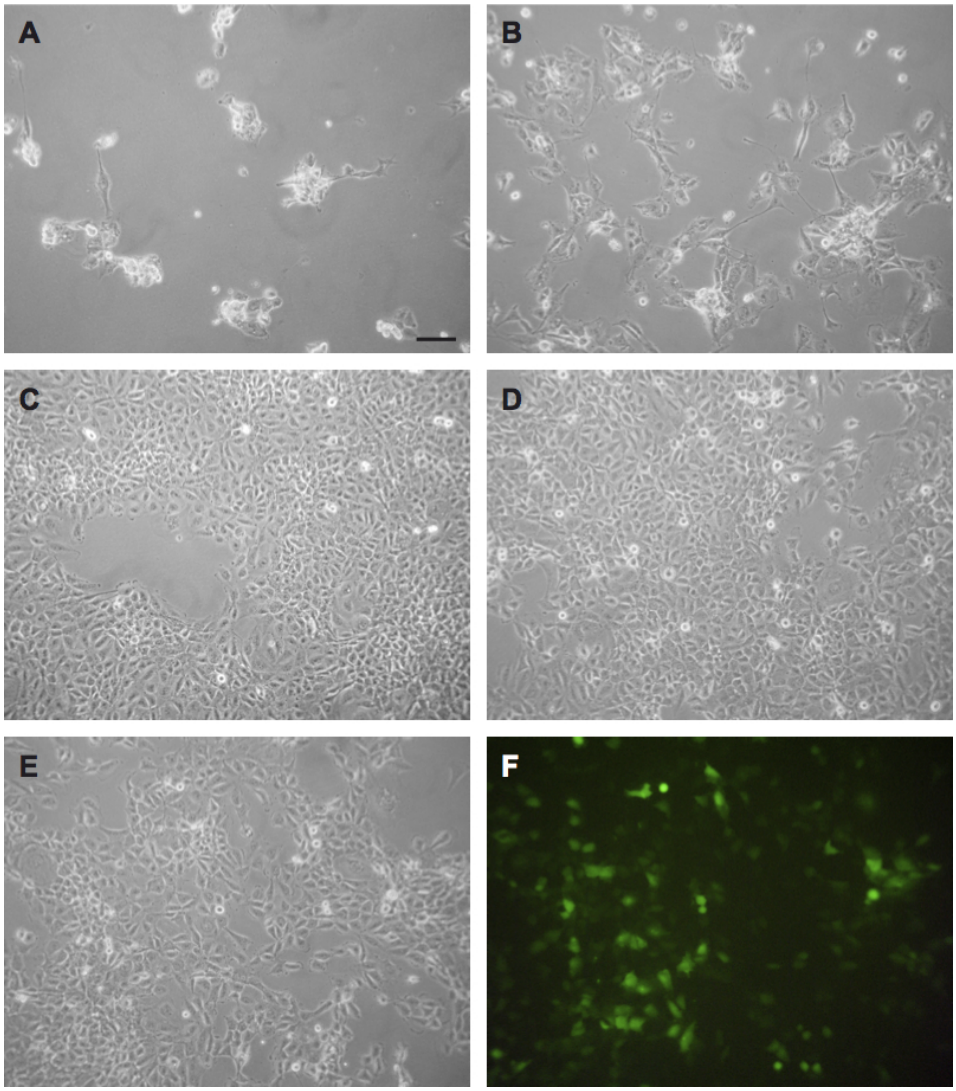

Figure 9.5.: *WISP1 gene-silencing in Tc28a2 chondrocytes on day 8 after transduction. (A) shRNA2 transduction results in cell death and thus reflect remarkable differences compared to the control samples (C, D, E). (B) shRNA5 transduced cells show similar effects, manifesting in cell death, but with slightly decelerated compared to the shRNA2 transduced cells. The scrambled (C), pure vector (D) and GFP control assays show entire proliferation and no optical differences among each other. Scale bar 100m.*

9.4. WISP1 gene-silencing in additional cell lines connected to the musculoskeletal system

Supplementary experiments of WISP1 gene-silencing were performed in the human chondrocyte cell line (C28I2), two immortalized MSC cell lines (Tert4, Tert20) and the human osteoblast cell line hFOB. During these experiments, same conditions including medium, incubation and handling were warranted. Two different shRNA constructs (shRNA2 and shRNA5) were used to reduce the endogenous amounts of both transcript variants of WISP1. Two negative controls (scrambled and pure vector) were used to observe cellular differences between WISP1 down-regulated and control assays. GFP was used as a positive control for measuring transfection and transduction efficiency. Figure 9.6 illustrates all corresponding experiments for each cell line. The first column (A1-A5) indicates cellular effects within C28I2 chondrocytes on the eighth day after transduction. Similar to the experiments in the Tc28a2 chondrocyte cell line, shRNA2 (A1) and shRNA5 (A2) transduced C28I2 cells died a few days after transduction. Both negative controls (scrambled A3, pure vector A5) showed an expected proliferation and the GFP control confirmed a successful transduction under exposure to UV-light (A4). Total RNA of all samples was isolated on day 8 to verify the down-regulation of both transcript variants of WISP1 with RT-PCR analysis (A6). Both, shRNA2 and -5 transduced cells show a remarkable reduction in the WISP1-T1 and -T2 mRNA levels, compared to the control samples. Similar outcomes were achieved for both immortalized MSC cell lines Tert4 (B1-B6) and Tert20 (C1-C6) and the osteoblast cell line hFOB (D1-D6). All cell types displayed the same cell characteristics in the absence of WISP1 compared to their control assays. RT-PCR analyses confirmed the reduction of the endogenous amounts of both transcript variants (B6, C6, D6).

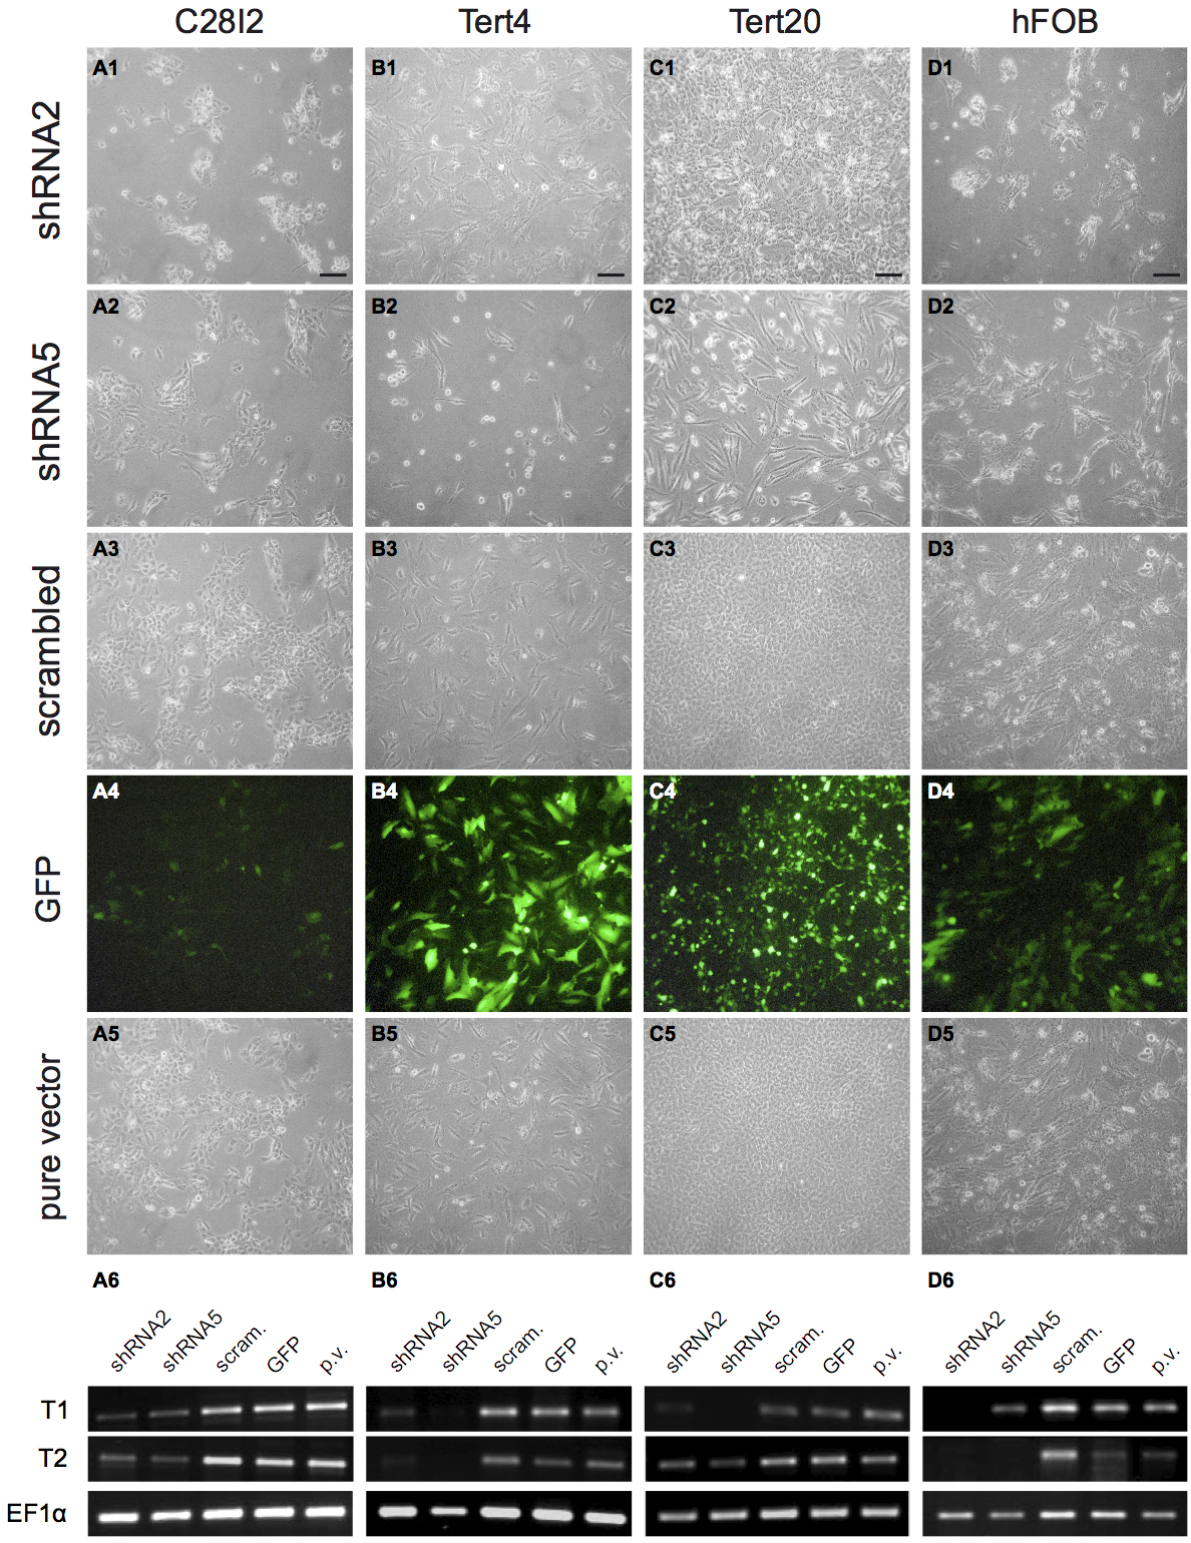

Figure 9.6.: *WISP1 down-regulation in the cell lines C28I2, Tert4, Tert20 and hFOB. In all present experiments, shRNA2 (A1, B1, C1 and D1) and shRNA5 (A2, B2, C2 and D2) transduced cells displayed the same cell characteristics. Eight days after transduction, scarcely viable cells were observable in all WISP1 down-regulated assays. In contrast, cells of the scrambled (A3, B3, C3 and D3) and pure vector (A5, B5, C5 and D5) control assays show an expected proliferation during the whole week. The GFP control confirmed a successful transduction in all cell lines (A4, B4, C4 and D4). Scale bar=100μm. RT-PCR analyses of total isolated RNA revealed a down-regulation of both transcript variants of WISP1 (A6, B6, C6 and D6). The mRNA levels of the housekeeping gene EF1α were used as internal controls.*

9.5. WISP1 gene-silencing in primary bone marrow derived hMSCs

To investigate cell characteristics of WISP1 depleted primary cells, additional experiments of WISP1-T1 and -T2 gene-silencing were performed in human bone marrow derived MSCs. Precedent work confirmed an continuous expression of both variants in 12 different hMSC donors (Fig. 8.1). Similar to the previously described experiments, two different shRNA constructs (shRNA2 and shRNA5) as well as three different controls (scrambled, GFP, pure vector) were used to compare WISP1 mRNA levels and cell characteristics. Figure 9.7 illustrates related optical differences between knock-down and control assays, like they were exhibited in the immortalized hMSC cell lines Tert4 and Tert20 (Fig. 9.6).

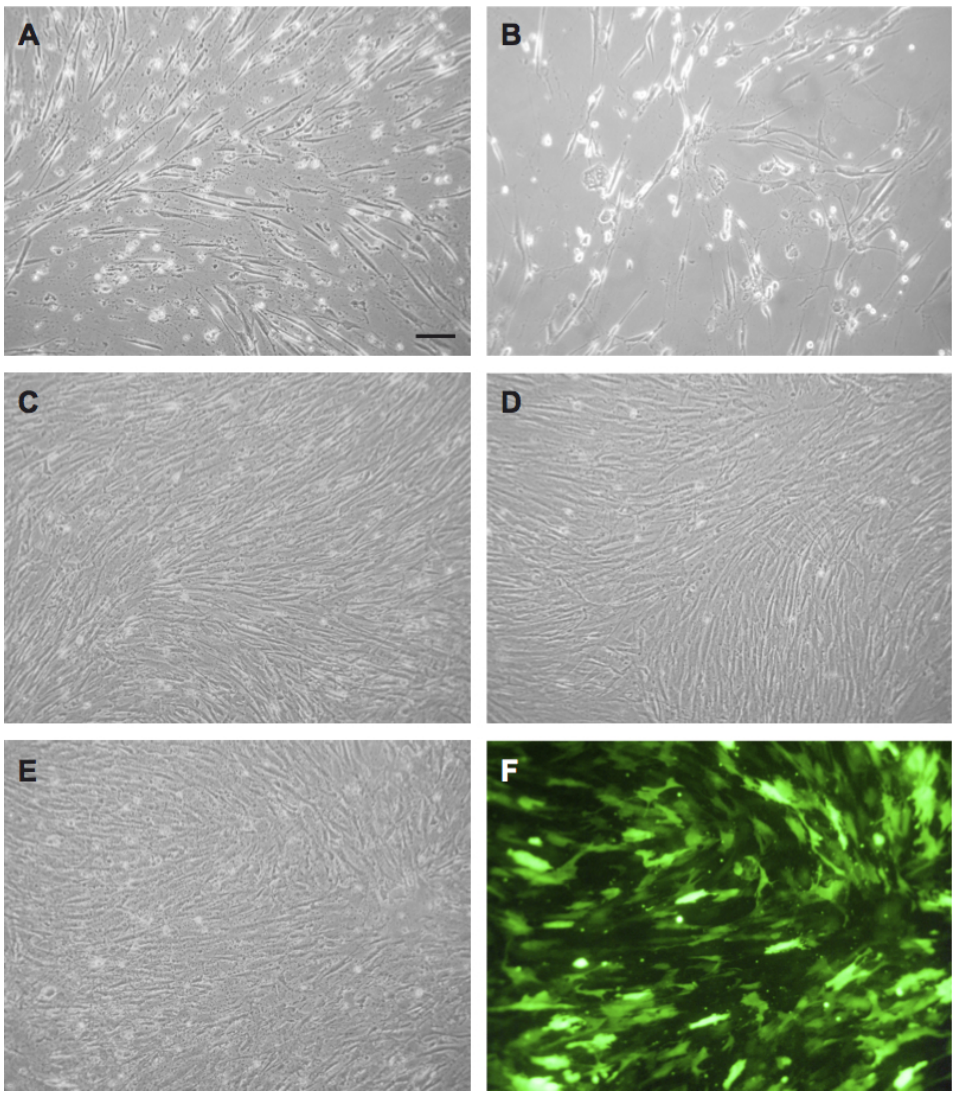

Figure 9.7.: *Microscopy of WISP1 down-regulation in primary hMSCs. Eight days after transduction, shRNA2 (A) and shRNA5 (B) transduced cells show distinct aberrant cell characteristics compared to the three control samples (C, D, E). Only few viable cells were observable while the scrambled (C), pure vector (D) and GFP control assays show entire proliferation and no optical differences among each other. Under exposure to UV-light GFP exhibits a bright, green fluorescence, which confirmed a successful virus transduction (F). Scale bar=*$100\mu m$.

However, shRNA2- and shRNA5 transduced hMSCs started to detach a few day after the transduction was performed. Cells transduced with shRNA5 (B) show slightly more optical differences than shRNA2 (A) transduced cells, but the optical effect was remarkably on day eight in both assays. All three controls (scrambled (C), pure vector (D) and GFP (F)) showed an expected proliferation within one week. Under exposure to UV-light, GFP visualized the successful transduction after eight days (F).

Total RNA of each sample was isolated and RT-PCR with subsequent densitometric analyses were performed to validate the successful down-regulation of WISP1-T1 and-T2 in the shRNA transduced assays (Fig. 9.8). The endogenous amounts of both transcript variants were significantly decreased in shRNA5 transduced cells. In contrast, all control samples showed expected mRNA levels of both transcript variants. Additional experiments were performed using shRNA5-, scrambled- and GFP constructs to confirm the down-regulation of WISP1 in four different hMSC donors. RT-PCR and subsequent densitometric analyses of the corresponding gel bands enabled a validation of a significant down-regulation of both WISP1 transcript variants (Fig. 9.8; Tab. 9.1).

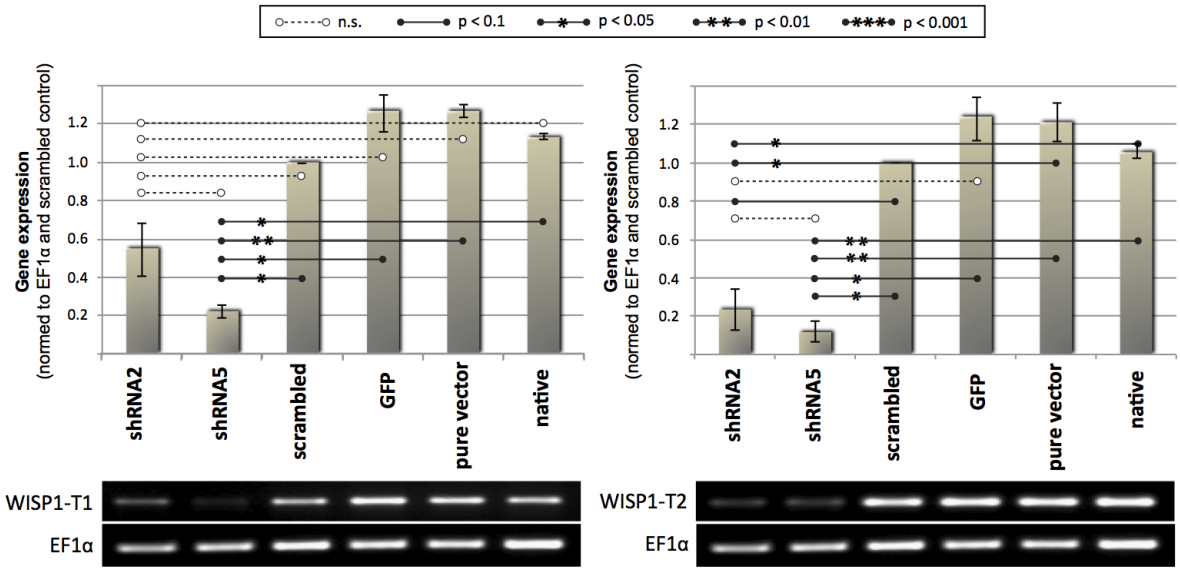

Figure 9.8.: *Densitometric analysis of RT-PCR bands from WISP1 down-regulation in primary hMSCs (n=4). Left: WISP-T1, right: WISP1-T2. The mRNA levels of the housekeeping gene EF1α were used as internal controls. Densitometric analysis of the corresponding gel bands revealed significant down-regulation of both transcript variants of WISP1. Displayed is the mean of densitometric measures, with the %SEM indicating error bars.*

Table 9.1.: *Results of the t-tests for all relevant comparisons between WISP1 down-regulation by shRNA2 and shRNA5 in hMSCs and the corresponding controls. The t-tests were conducted with paired samples and two sided. A p-value correction by fdr has been applied according to the number of comparisons. Differences were considered significant when the corrected p-value was <0.05 (∗), <0.01 (∗∗) and <0.001 (∗ ∗ ∗). N_S=Number of samples, df=degrees of freedom, p-adj.=corrected p-values, N_C=Number of comparisons corrected for p-adj.*

MICROARRAY ANALYSES

10.1. Microarray analysis of WISP1-T1 and -T2 silenced hMSCs

Assays with a reduced WISP1 expression (n=3) and the corresponding scrambled control assays (n=3) were performed in hMSCs simultaneous with the shRNA5- and scrambled control constructs. Total RNA was isolated at the fourth day after transduction to detect gene regulations in an early stage of cell death. RNA specimers were visualized and verified with gel electrophoresis. Figure 10.1 illustrates the purity of the 28s RNA (5.1kb) and 18s RNA (1.9kb) of all six samples.

Affymetrix microarray analyses were performed with the HG-U133+2.0 GeneChip and subsequent utilized with the statistical software R and its additional component for microarray analyses, namely Bioconductor (Gentleman et al. 2004b; R Development Core Team 2010). Raw data was visually quality controlled and the RNA degradation plot was used to determine the quality of all samples (Fig. 10.2 (A)). Mean intensities of all RNA specimens were lower in RNA parts of the 5' region compared to mean intensities of parts within the 3' region. However, all RNA samples reflect the same expected intensity gradients and were used for further analyses. In addition, Figure 10.2 illustrates box plot (B) and density plot (C) results of the raw data prior to the normalization steps.

Subsequently, three normalization steps were applied for each sample. Firstly, normalization using the robust multi-array average expression measure (RMA) with background correction; secondly, using the quantiles without background correction and thirdly the variance stabilization and normalization (VSN) with background correction. Figure 10.3 reflects box plot (A) and density plot (B) results of the raw data after the three normalization steps were per-

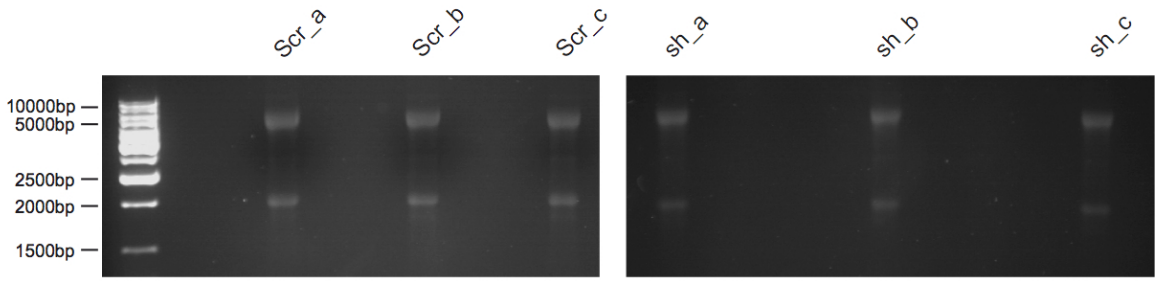

Figure 10.1.: *Gel electrophoresis results after RNA isolation from hMSCs. Displayed are 28s RNA (5.1kb) and 18s RNA (1.9kb) amounts, previously isolated from scrambled control transduced samples and shRNA5 transduced assays.*

formed. The RMA method yielded the best outcome, which was determined by comparison of the density plots, and was used for the following analyses.

10.1.1. Gene expression pattern after WISP1 gene-silencing in hMSCs

The Affymetrix GeneChip HG-U133+2.0 was able to detect regulation of 54.675 probe sets. Linear models for microarray data were fit to expression data using the R package limma. The AFFX cut-off (maximum differentially expressed AFFX labelled probe set as threshold) was used to reduce the data to the most significant probe sets. Thereby, comparison between WISP1 deficient (shRNA5) and sufficient (scrambled control) hMSCs revealed 522 differentially expressed probe sets corresponding to 456 genes. 210 probe sets (corresponding to 179 genes) were significantly up-regulated in shRNA5-transduced samples, while 312 probe sets revealed a significant down-regulation (corresponding to 277 genes). The top-ranked 25 differentially expressed genes detectable during the absence of WISP1 in hMSCs are listed according to their descending statistical score (logFc) in table 10.1.

Eight of the top ranked up-regulated genes were involved in immuno-regulatory processes. Additional, TNFSF10 (also known as TRAIL) - one of the major death ligands - is the fifth highest ranked up-regulated gene detected directly after WISP1 down-regulation. Detailed distribution of regulated probe sets including the logFc range and the adequate p-values are listed in the appendix A due to their degree of regulation (logFc) from highest up-regulation to highest down-regulation.

10.1.2. Gene ontology analysis

Significantly regulated genes of the array data were analysed for their affiliation regarding the main Gene Ontology (GO) categories biological process, cellular component and molecular function as well as for KEGG pathway over-representation (Ashburner et al. 2000; Falcon and Gentleman 2007b; Gentleman et al. 2004a; Harris et al. 2004; Ogata et al. 1999; R Development Core Team 2010). A detailed distribution regarding the different GO terms and KEGG pathway over-representation is listed in the appendix B due to the corresponding p-value for each subclass within the different terms. An overview of these results is provided in table 10.2. The analysis revealed several important cellular processes, affected subsequent to the down-regulation of WISP1. For example, a conspicuous cluster of differentially expressed genes belonged to different subclasses of immune-response (e.g. innate immune-response and positive regulation of interferon-beta production) was discovered in the GO-class of biological process. Similarly, regulations associated with e.g. apoptosis (induction of apoptosis and positive regulation of apoptosis) and focal adhesion could be assigned along the main GO-categories. Gene regulation in subclasses of higher interest will be observed in detail in subsequent sections.

10.1.3. Selection of regulated genes involved in immuno-regulatory processes

Microarray data analysis and additional GO classification, exhibited a remarkable cluster of gene regulations involved in immuno-regulatory processes. All differentially expressed genes were detected subsequently after the down-regulation of WISP1 took place in three different hMSC donors. Conspicuously, every probe set corresponding to the cluster of immune-responsive genes was up-regulated directly after the absence of WISP1 was enforced. Figure 10.4 illustrates these gene regulations by colour-coding in a so called heat map. The first three columns reflect regulations of the three scrambled control samples, whereas the following three columns display the corresponding WISP1 gene-silencing experiments. In this context, white represents high expression (over yellow and orange as medium expression) and red low

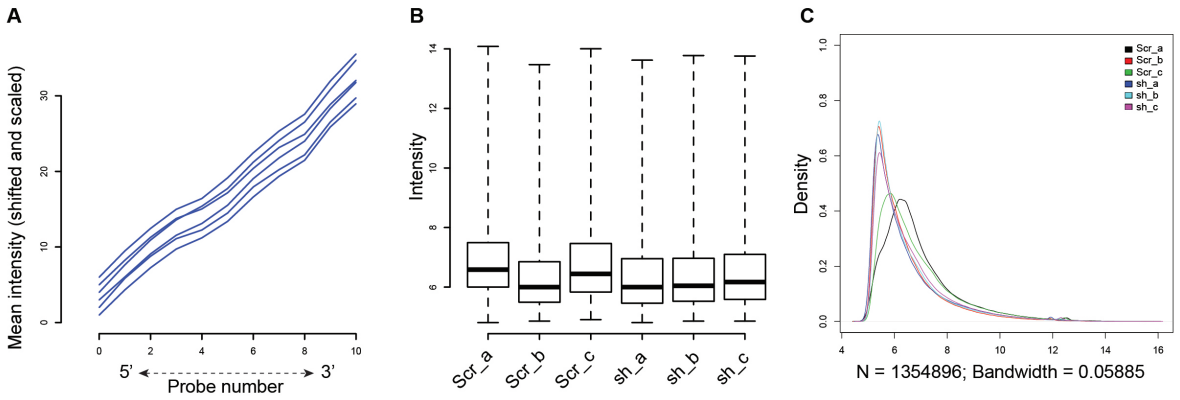

Figure 10.2.: *Diagnostic plots of microarray raw data prior to normalization. (A) RNA degradation from 5' to 3' end of the probe sets. Displayed are mean intensity values for each array. All samples were comparable according to their ascendent slope and parallelity. (B) and (C) displayed the distribution of raw expression intensities by box plot and density plot, respectively.*

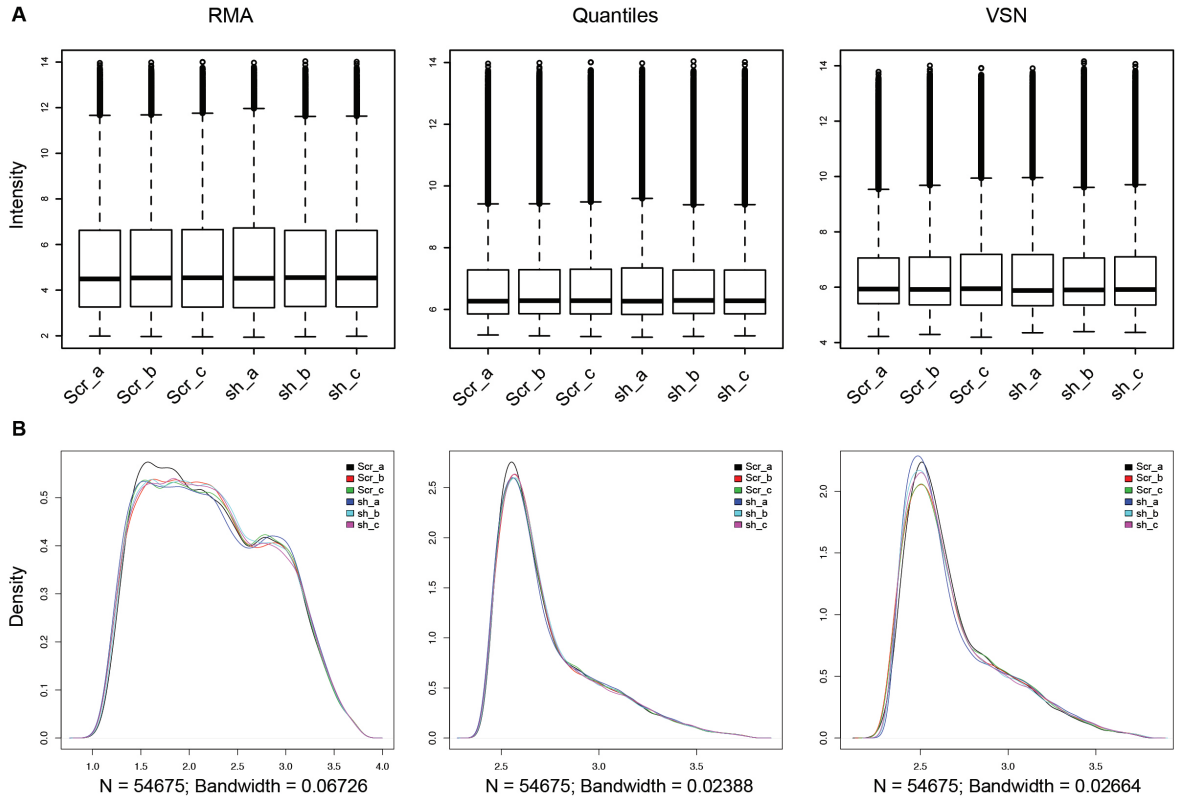

Figure 10.3.: *Diagnostic plots of microarray data after normalization. (A) Box plot distributions and (B) densities of normalized expression intensities. Within both subfigures, the three columns are the different applied normalization methods RMA, quantiles and VSN.*

Table 10.1.: *25 top-ranked genes differentially expressed after WISP1 down-regulation in hMSCs. Genes are listed according to their descending statistical score (logFc) with additional information regarding the number of regulated probe sets (N) and the corresponding adjusted (corrected for multiple comparisons) p-value. Thereby, positive values indicate fold changes of up-regulated whereas negative values state fold changes of down-regulated gene expression in shRNA5 transduced samples compared to the corresponding controls. Specified logFc and p-value belongs to the highest regulated probe set in case of more than one regulated probe set.*

Symbol	Gene name	logFC	adj. p-val.	N

ACTA2	actin, alpha 2, smooth muscle, aorta	-3.01	$4.4x10^{-6}$	1
KCTD20	potassium channel tetramerisation domain containing 20	-3.06	$1.8x10^{-6}$	2

Table 10.2.: *Gene Ontology (GO) analysis and KEGG pathway over-representation. All 456 significantly regulated genes, detected during the WISP1 array data analysis in hMSCs, were continuative assigned to GO terms and KEGG signalling pathways. Illustrated are, in addition to the corresponding subclass name, the expected count, actual count and overall number of genes (N) associated to the GO/KEGG-term. These values are related to and corrected by the total number of all and differentially expressed corresponding genes present on the chip. Odds-ratio of corrected values is provided by the fraction (N/actual count). Corresponding p-values are results of the hyper-geometric tests.*

Figure 10.4.: *Selection of regulated genes involved in immuno-regulatory processes. Levels of gene expression are visualized by colour-coding, i.e. heat-colours with white representing high expression, over yellow and orange as medium expression and red representing low expression of the corresponding probe set. Values are normalized by rows (Z-score). Gene names are aligned beside the rows, with additional information regarding probe set IDs, degree of regulation (logFC) and the corresponding p-value. Sample names are presented over each column. Scr=scrambled control sample, sh=WISP1 down-regulated sample, logFC=logarithmic fold change, p-val.=adjusted p-value.*

10.1.4. Selection of regulated genes involved in cell survival and apoptosis

Eligible to the observed optical effect of cell death directly after the WISP1 down-regulation occurred, the bioinformatical investigation of the data sets identified also a cluster of differentially expressed genes associated with cell survival and/or apoptosis. In this section all statistical significant gene regulations were observed regarding their association with apoptosis and/or cell survival and independently of the previous used AFFX-cut off, but with high attention to the logFC and the corresponding adj. p-value. In all three comparisons, WISP1 down-regulation specifically affected genes important for both main apoptosis signalling cascades: the extrinsic- and intrinsic-mediated apoptosis.

Subsequent, the heat map clearly illustrates this cluster of gene regulations by colour-coding in all hMSC samples (Fig. 10.5). The first three columns reflect regulations in the control samples and the following three columns the corresponding gene regulation after the WISP1 down-regulation. Adapted to table 10.3, genes are listed according to their effectiveness connected to cell survival and/or apoptosis. Genes with regulations of more than one probe set were reduced to the probe set with the highest logFC. Not all genes in this cluster show regulations with the consequence of cell death. Three members (EIF2AK3, BOK and CASP2) are regulated in the opposite direction and are listed for the sake of completeness.

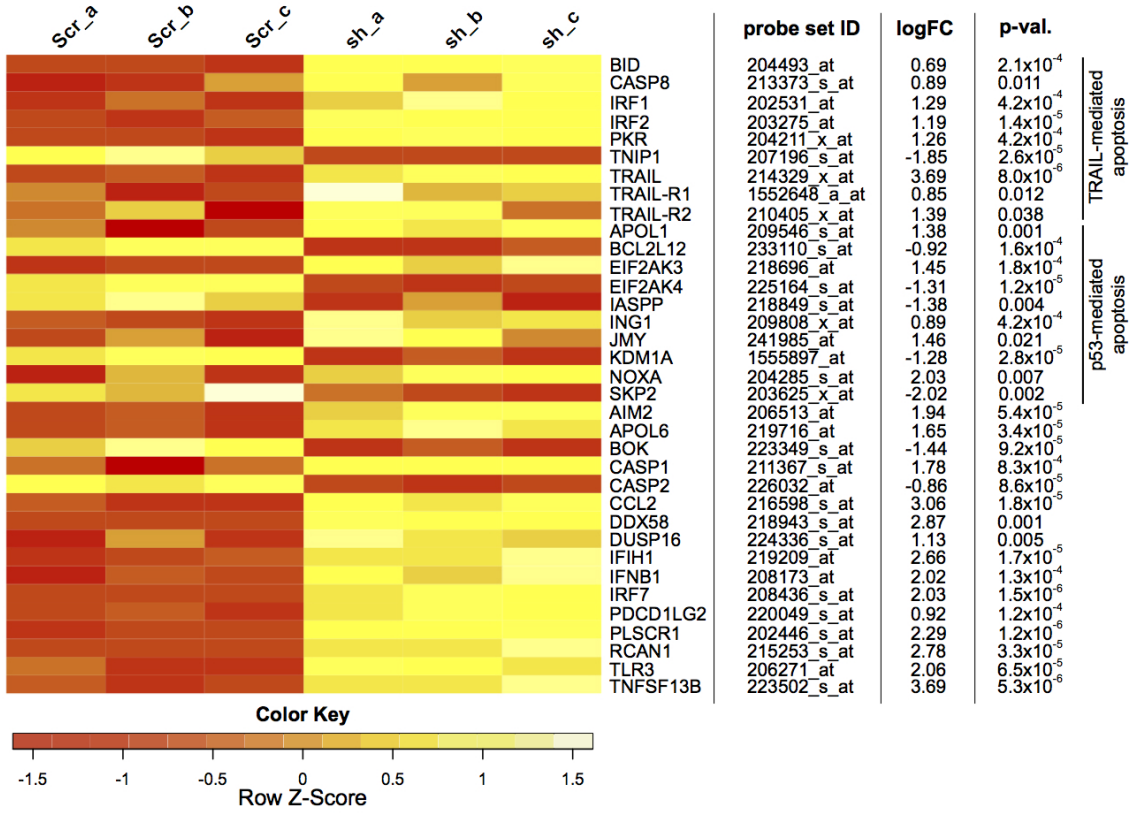

Figure 10.5.: *Selection of apoptosis responsive gene regulations. Genes are listed according to their effectiveness connected to cell survival and/or apoptosis. Levels of gene expression are visualized by colousubclassr-coding, i.e. heat-colours with white representing high expression, over yellow and orange as medium expression and red representing low expression of the corresponding probe set. Values are normalized by rows (Z-score). Gene names are aligned beside the rows, with additional information regarding probe set IDs, degree of regulation (logFC) and the corresponding p-value. Sample names are presented over each column. Scr=scrambled control sample, sh=WISP1 down-regulated sample, logFC=logarithmic fold change, p-val.=adjusted p-value.*

Table 10.3.: *Selection of apoptosis responsive gene regulations. Genes are listed according to their effectiveness connected to cell survival and/or apoptosis. The first nine members are assigned to the TRAIL mediated apoptosis, whereas the ten adjacent listed genes are clearly correlated to the p53 mediated apoptotic pathway. Columns (from left to right) describe gene symbols, gene names, number of regulated probe sets (N) and a short summary of the way of function in relation to cell death.*

Symbol	Gene name	N	Function Related to Cell Death
BID	BH3 interacting domain death agonist	1	pro-apoptotic member of the BCL2 family. Triggers cytochrome c release by shutteling to the outer mitochondrion membrane after CASP8 cleavage (Gross et al. 1999; Li et al. 1997; Liu et al. 1996; Renshaw et al. 2004)
CASP8	caspase 8, apoptosis-related cysteine peptidase	1	key component of the extrinsic mediated apoptosis (Ashkenazi and Dixit 1998; Budihardjo et al. 1999)
IRF1	interferon regulatory factor 1	2	expression of either IRF-1 or IRF-2 results in cleavage of caspase-8, -3 and -7 and promotes extrinsic mediated apoptosis (Chow et al. 2000; Stang et al. 2007; Wu et al. 2010)
IRF2	interferon regulatory factor 2	1	expression of either IRF-1 or IRF-2 results in cleavage of caspase-8, -3 and -7 and promotes extrinsic mediated apoptosis (Chow et al. 2000)
PKR	eukaryotic translation initiation factor 2-alpha kinase 2	2	over-expression induces apoptosis (Kibler et al. 1997; Lee and Esteban 1994), up-regulate the expression of the apoptotic receptor Fas (Takizawa et al. 1995)
TNIP1	TNFAIP3 interacting protein 1	1	inhibits TNF-induced apoptosis (Oshima et al. 2009; Wullaert et al. 2005)
TRAIL (TNSF10)	TNF-related apoptosis-inducing ligand	3	Major death ligand, rapidly induces apoptosis in a wide variety of transformed cell lines (Marsters et al. 1996; Wiley et al. 1995), TRAIL-expressing MSCs were able to significantly reduce tumor growth (Loebinger et al. 2009)

Table 10.3.: (...continued)

Symbol	Gene name	N	Function Related to Cell Death
TRAIL-R1 DR4, TNSFRSF10A	TNF-related apoptosis-inducing ligand receptor 1	3	contains a cytoplasmic death domain and activates apoptosis by binding of TRAIL (Pan et al. 1997)
TRAIL-R2 DR5, TNSFRSF1B	TNF-related apoptosis-inducing ligand receptor 2	2	contains a cytoplasmic death domain and activates apoptosis by binding of TRAIL (Sheridan et al. 1997; Walczak et al. 1997)
APOL1	apolipoprotein L, 1	1	p53 downstreem target in p53 mediated apoptosis, induced autophagic cell death. (Wan et al. 2008; Zhaorigetu et al. 2008)
BCL2L12	BCL2-like 12 (proline rich)	1	anti-apoptotic member of the BCL2 family, inhibits caspases 3 and 7 in the cytoplasm and p53 in the nucleus (Stegh et al. 2007; Stegh and Depinho 2011)
EIF2AK3	eukaryotic translation initiation factor 2-alpha kinase 3	1	down-regulation promotes apoptosis via activation of p53 signal cascade (Liu et al. 2010)
EIF2AK4	eukaryotic translation initiation factor 2 alpha kinase 4	1	down-regulation promotes apoptosis via activation of p53 signal cascade (Liu et al. 2010)
IASPP	Inhibitor of ASPP protein	1	one of the most evolutionarily conserved inhibitors of p53 (Ahn et al. 2009)
ING1	inhibitor of growth family, member 1	2	Part of the p53 apoptotic pathway, stabilizes p53 by disrupting the the Interaction with p53 inhibitor MDM2 (Garkavtsev et al. 1998; Leung et al. 2002; Thalappilly et al. 2011)
JMY	junction mediating and regulatory protein, p53 cofactor	1	pro-apoptotic cofactor of p53 (Shikama et al. 1999)
KDM1A	lysine (K)-specific demethylase 1A	1	the histone lysine-specific demethylase mediates p53 demethylation and inhibts p53 mediated apoptosis (Huang et al. 2007; Scoumanne and Chen 2008)

...continues on next page

Table 10.3.: *(...continued)*

Symbol	Gene name	N	Function Related to Cell Death
NOXA	PMA-induced protein 1	2	pro-apoptotic member of the BCL2 family, mediator of p53-dependent apoptosis (Eferl et al. 2003; Kim et al. 2004; Oda et al. 2000; Seo et al. 2003)
SKP2	S-phase kinase-associated protein 2 (p45)	1	suppresses p300-mediated acetylation and activation of apoptosis via p53 (Kitagawa et al. 2008)
AIM2	absent in melanoma 2	1	Interaction with ASC (via pyrin-card-domain-binding) leads to an activated inflammasome and cell death via CASP1 (Fernandes-Alnemri et al. 2007; Hornung et al. 2009)
APOL6	apolipoprotein L, 6	4	induced mitochondria-mediated apoptosis in human colon cancer cells (Liu et al. 2005; Zhaorigetu et al. 2011)
BOK	BCL2-related ovarian killer	1	pro-apoptotic member of the BCL2 family, interacts with some anti-apoptotic members of the family like MCL1 (Hsu and Hsueh 1998; Hsu et al. 1997; Yang et al. 1995)
CASP1	caspase 1	5	is involved in inflammasome formation and cell death (Fernandes-Alnemri et al. 2007; Friedlander et al. 1996)
CASP2	caspase 2	2	activated by a variety of apoptotic stimuli of stress induced apoptosis (Harvey et al. 1997; Tinel and Tschopp 2004; Zhivotovsky and Orrenius 2005)
CCL2	chemokine (C-C motif) ligand 2	1	causes cell death by inducing oxidative stress (Xia et al. 2010; Younce and Kolattukudy 2010)
DDX58	DEAD (Asp-Glu-Ala-Asp) box polypeptide 58	3	triggers apoptosis as part of an antiviral host response (Besch et al. 2009; Hornung et al. 2009; Peng et al. 2009)

...continues on next page

Table 10.3.: *(...continued)*

Symbol	Gene name	N	Function Related to Cell Death
DUSP16	dual specificity phosphatase 16	2	inactivation via ROS mediates activation pro-apoptotic JNK signalling (Kiessling et al. 2010)
IFIH1	interferon induced with helicase C domain 1	1	triggers apoptosis as part of an antiviral host response (Peng et al. 2009)
IFNβ1	interferon, beta 1, fibroblast	1	produktion (triggered by TLR3 and IFIH1 signalling) leads to apoptosis via multiple BH3-only proteins (Marraco et al. 2011)
IRF7	interferon regulatory factor 7	1	function as an effector of BRCA1/IFNγ mediated apoptosis (Buckley et al. 2007)
PDCD1LG2	programmed cell death 1 ligand 2	2	programmed cell death 1 ligand 2 (genecards)
PLSCR1	phospholipid scramblase 1	2	expression through STAT1 requires activation of PKCδ and JNK. Increased intrinsic mediated apoptosis after DNA damage (Zhao et al. 2005)
RCAN1	regulator of calcineurin 1	2	facilitates neuronal apoptosis through caspase-3 activation (Sun et al. 2011)
TLR3	toll-like receptor 3	1	activation triggered the signalling of both the extrinsic and intrinsic apoptotic pathways (Marraco et al. 2011; Sun et al. 2011)
TNFSF13B	tumor necrosis factor (ligand) superfamily, member 13b	2	mediates apoptosis via caspase 3 activation, also activates NFκB and JNK (Mukhopadhyay et al. 1999)

10.1.5. Reevaluation by semi-quantitative RT-PCR

Amongst regulated genes, a selection of twelve were chosen for reevaluation by semi-quantitative RT-PCR and densitometric evaluation of RT-PCR bands on agarose gels. These genes, listed in table 10.4, were selected due to their high fold change obtained by microarray analysis with high attention to their functional properties that may be potentially relevant during apoptosis, immuno-regulatory processes or in consideration to their linkage concerning interactions with the ECM.

Reevaluation by RT-PCR was accomplished with the same RNA samples, previously used for the microarray analysis. The regulation of twelve gene products could be confirmed according to the microarray findings (Fig. 10.6; Tab. 10.5).

Table 10.4.: *Selection of genes for reevaluation. From left to right: probe set IDs, gene symbols, gene names, degree of regulation (logFC) and the corresponding p-value. Genes are listed alphabetically and according to their descendent statistical score in cases where more than one probe set is regulated.*

Additional experiments of WISP1 gene-silencing were performed with a supplemental hMSC donor to determine gene regulations, of the previously validated genes, over time. Therefore, total RNA was isolated on d3 to d7 after transduction with shRNA5 and srambled control constructs. Thereby, day four reflects the gene expression patterns of the previously performed microarray analysis. RT-PCR analysis revealed time dependent regulations of APOL1, DDX58, IFIH1, IFNβ1, ISG15, NOXA and TRAIL. Interestingly, all of them are linked to apoptotic pathways and clearly increased in their up-regulation from d3 to d7 (Fig. 10.7).

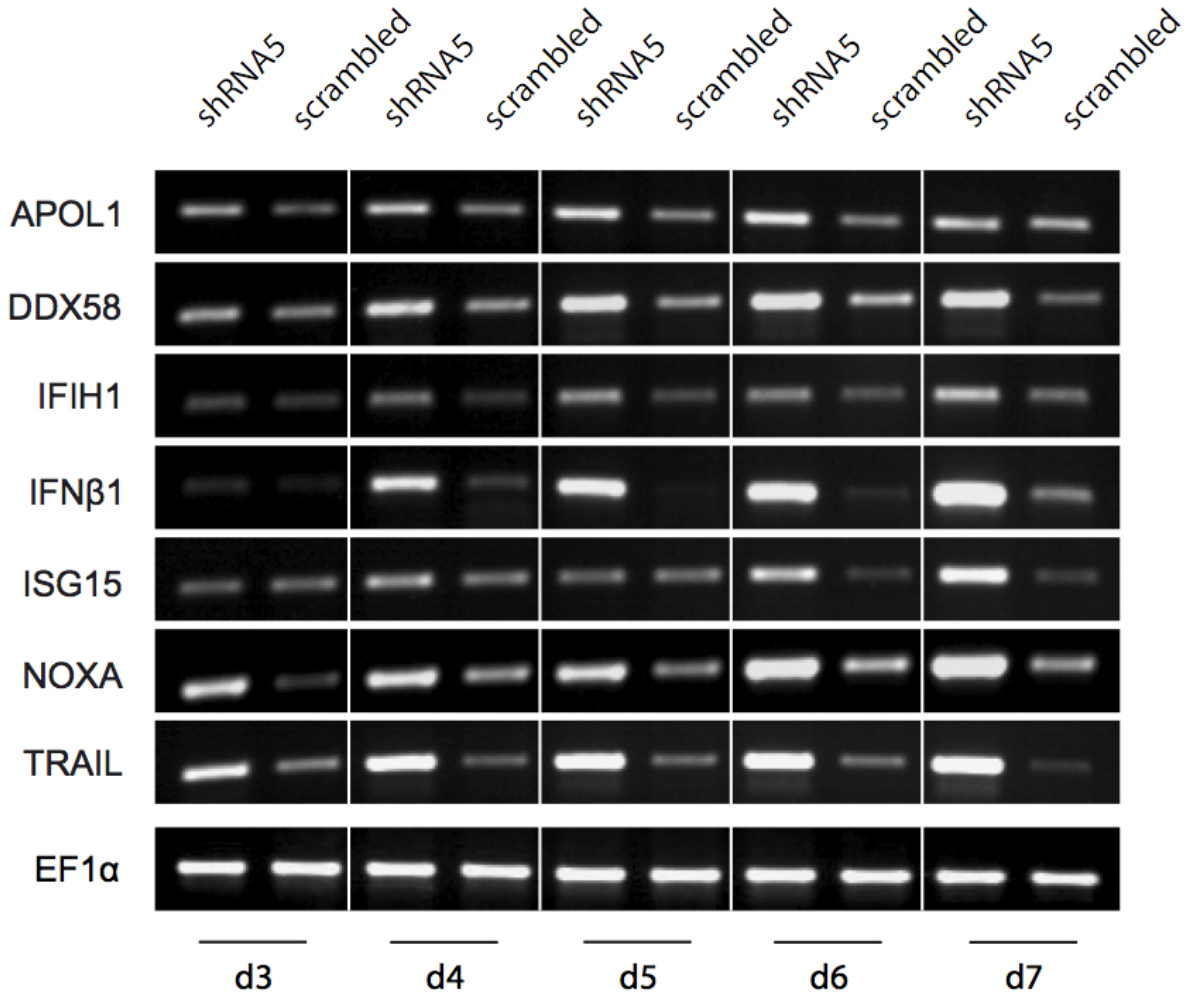

Figure 10.7.: *RT-PCR of gene regulations after WISP1 down-regulation in hMSCs over time. Total RNA was obtained on d3 to d7 after transduction with shRNA2 and scrambled control constructs. Seven of the previously reevaluated genes show additional an increased up-regulation over time. The mRNA levels of the housekeeping gene EF1α were used as internal controls.*

10.2. Microarray analysis of WISP1-T1 and -T2 down-regulated Tc28a2 chondrocytes compared to control cells

Further microarrays with HG-U133+2.0 GeneChips were performed by usage of RNA samples collected from WISP1 gene-silencing experiments (n=5) and scrambled control assays (n=5) in Tc28a2 chondrocytes. Previously, cells were transduced with the shRNA2- and scrambled control constructs and total RNA isolation took place on the fourth day after transduction. The RNA specimer visualization, as well as the raw data inspection was performed simultaneous to the procedure of the previously described microarray analysis in hMSCs (Sec. 10.1). All RNA samples shared the same expected intensity gradients and were used for further analyses. Three normalization steps were applied for each of the samples and comparison of the density plots revealed the RMA method as the best normalization. Using the R package limma and the AFFX cut-off, the analyses resulted in 1687 differentially regulated probe sets, corresponding to 1402 regulated genes. 493 of these probe sets (corresponding to 417 genes) show significantly up-regulation in WISP1 deficient chondrocytes whereas 1194 probe sets (corresponding to 985 genes) revealed a significant down-regulation. Detailed distribution of regulated probe sets including the logFC range and the adequate p-values are listed in the appendix C due to their degree of regulation from highest up-regulation to highest down-regulation. Table 10.6 reflects the top-ranked 25 differentially expressed genes, which were regulated directly after WISP1 down-regulation was present in the chondrocyte cell line Tc28a2.

10.2.1. Gene ontology analysis

Amongst regulated genes that were differentially expressed between WISP1 down-regulated (shRNA2) and control (scrambled) chondrocytes, microarray analyses detected several gene cluster with important cellular functions. Therefore, significantly regulated genes of the array data were analysed for their affiliation regarding the previously described main Gene Ontology (GO) categories and KEGG pathway over-representation. Table 10.7 shows a selection of these results with major attention to the corresponding p-values and odds-ratios. Many subclasses, associated with cartilage homeostasis, cell cycle-regulation and MAPK-signalling, could be detected in the main class of biological processes. Another interesting cluster comprised mitochondrion associated subclasses of cellular components and indicate a linkage of WISP1 depleted chondrocytes to mitochondrion interaction. Pathways, which can be directly linked to apoptosis or cell survival, like regulations within the apoptosis pathway as well as the regulation of MAPK-, ERB- and NOD-like receptor signalling were detected by KEGG pathway over-representation. Detailed distributions of different terms and KEGG pathway over-representation are listed in the appendix D due to the corresponding p-value for each subclass within the different terms.

Table 10.6.: *The 25 top-ranked genes differentially expressed after WISP1 down-regulation in chondrocytes. Genes are listed due to their degree of regulation from highest up-regulation to highest down-regulation. Similarly stated is information regarding the number of regulated probe sets and the corresponding adjusted p-value. The specified p-value belongs to the highest regulated probe set since more than one regulated probe set was detected.*

Table 10.7.: *Gene Ontology (GO) analysis and KEGG pathway over-representation. All 1402 significantly regulated genes, detected during the WISP1 array data analysis in Tc28a2 chondrocytes, were continuatively assigned to GO terms and KEGG signalling pathways. Illustrated are, in addition to the corresponding subclass name, the expected count, actual count and overall number of genes (N) associated to the GO/KEGG-term. These values are related to and corrected by the total number of all and differentially expressed corresponding genes present on the chip. The corresponding odds-ratio of corrected values is provided by the fraction (N/actual count). Corresponding p-values are results of the hyper-geometric tests.*

Beside pathways, which can be directly linked to apoptosis or cell survival, some other interesting regulations could be detected within KEGG pathway over-representation. Figure 10.8 reflects all significant (p-value$<$0.1) over-represented pathway regulations directly after WISP1 down-regulation was achieved. Five of these pathways are associated with different cancer types (e.g. leukemia, lung- and prostata cancer) and are also of higher interest in consideration with apoptotic signals during the absence of WISP1. Similarly, the influence of important cellular processes like cell cycle decisions can trigger apoptotic signals and thus leading to cell death. Apart of pathways with regard to the optical phenotype of WISP1 deficient chondrocytes, focal adhesion, the most significantly over-represented pathway in this analysis, is of main interest, since it supports the knowledge of the CCN connection and interaction with the ECM.

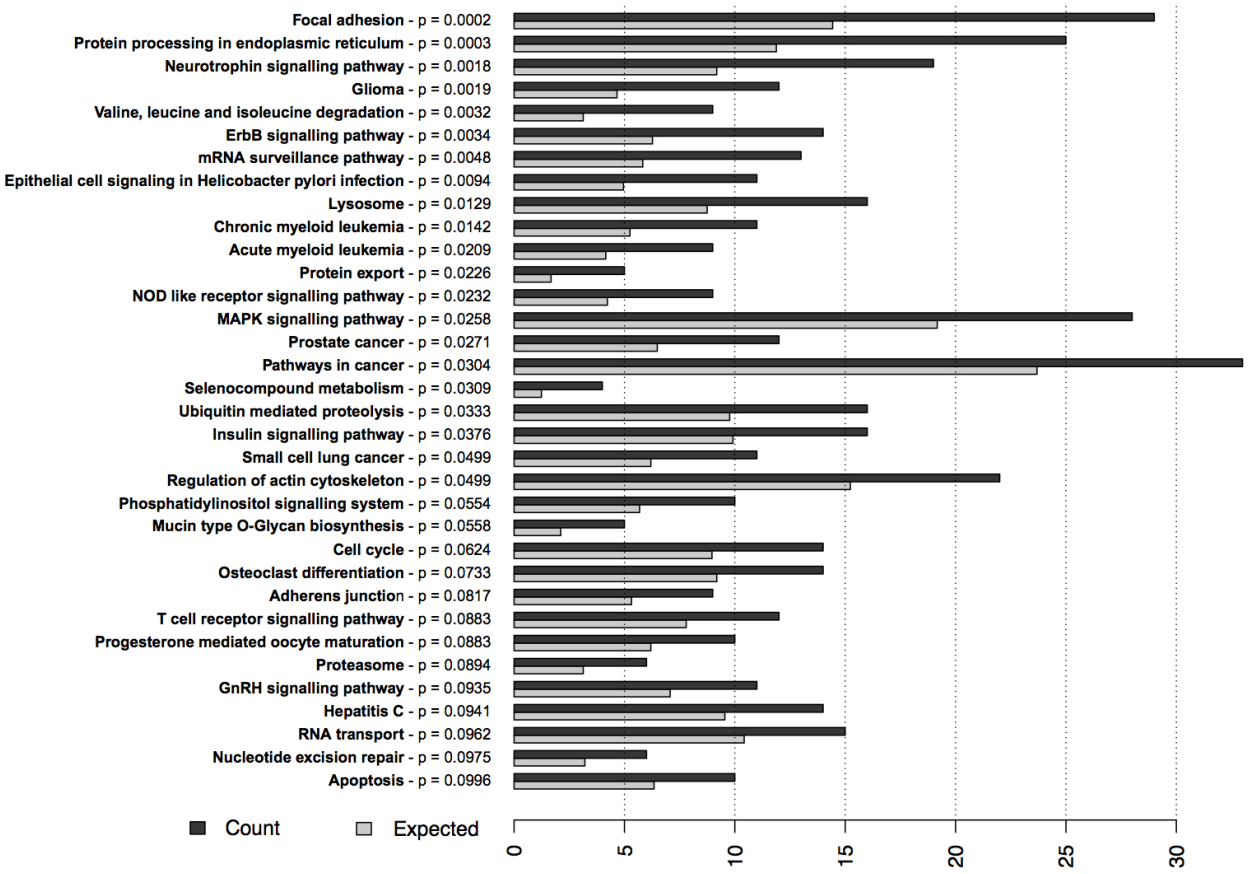

Figure 10.8.: *KEGG pathway over-representation. All 1402 significantly regulated genes were assigned to KEGG-signalling pathways. Illustrated are all pathways, which were over-represented according to their corresponding p-values. Grey bars indicate the expected count of gene regulations for each pathway, whereas black bars demonstrate the actual count. Corresponding p-values are results of the hyper-geometric tests.*

10.2.2. Differential expressed genes during MAPK-signalling cascades

Figure 10.9 comprises all gene regulations within the MAPK-signalling pathway (KEGG ID: 04010). This pathway regulation was detected with significance in several GO subclasses as well as by the KEGG pathway over-representation. The first five columns reflect regulations in the control samples and the following five columns the corresponding gene regulation after the WISP1 down-regulation. It is noticeable that the expression of most genes corresponding to the MAPK-signalling, are decreased directly after the down-regulation of WISP1 is apparent.

In supplement, we were able to visualize interaction patterns of the proteins corresponding to gene regulations on the basis of the KEGG database. Thus, not only overall regulation within a pathway, but also the interaction between the relevant molecules is of main interest. These interaction patterns are available for every pathway with the minimum of two different regulated genes per pathway. Not only the interaction itself between two or more pathway members is visualized, in fact the kind of interaction could be uncovered. Thus, we were able to exhibit e.g. indirect or direct effects, activation or inhibition, expression or repression as well as modifications like phosphorylation/dephosphorylation, methylation/ubiquitination and glycosylation. During the observation of the interaction patterns of all over-represented pathways, it was interesting that several of these pathways displayed no interaction of the corresponding differentially expressed molecules (data not shown). In contrast, the MAPK-signalling path-

way disclosed some interesting interactions between several differentially regulated members (Fig. 10.10). Some interactions could directly affect important cellular processes like proliferation and cell survival. Further, protein interactions that influence other pathways like cell cycle and apoptosis, which were over-represented in our analysis are of main interest and provide a foundation for further analysis.

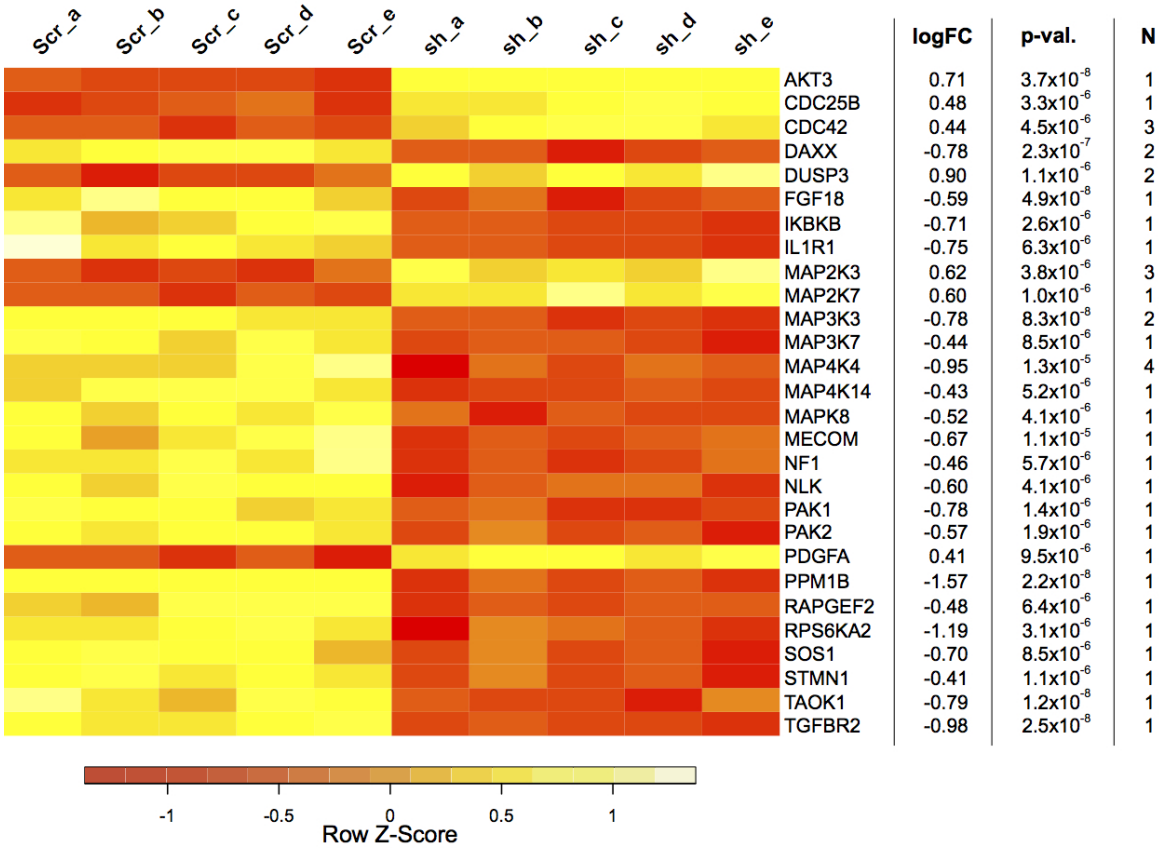

Figure 10.9.: *Heat map of gene regulations within the MAPK-signalling pathway. Levels of gene expression are visualized by colour-coding with white representing high expression, over yellow and orange as medium expression and red representing low expression of the corresponding probe set. Values are normalized by rows (Z-score). Gene names are aligned beside the rows, with additional information regarding degree of regulation (logFC), the corresponding adjusted p-value and the number of regulated probe sets. The highest regulated probe set was chosen for visualization in the case more than one regulated probe set was detected. Sample names are presented over each column. Scr=scrambled control sample, sh=WISP1 down-regulated sample, logFC=logarithmic fold change, p-val.=adjusted p-value.*

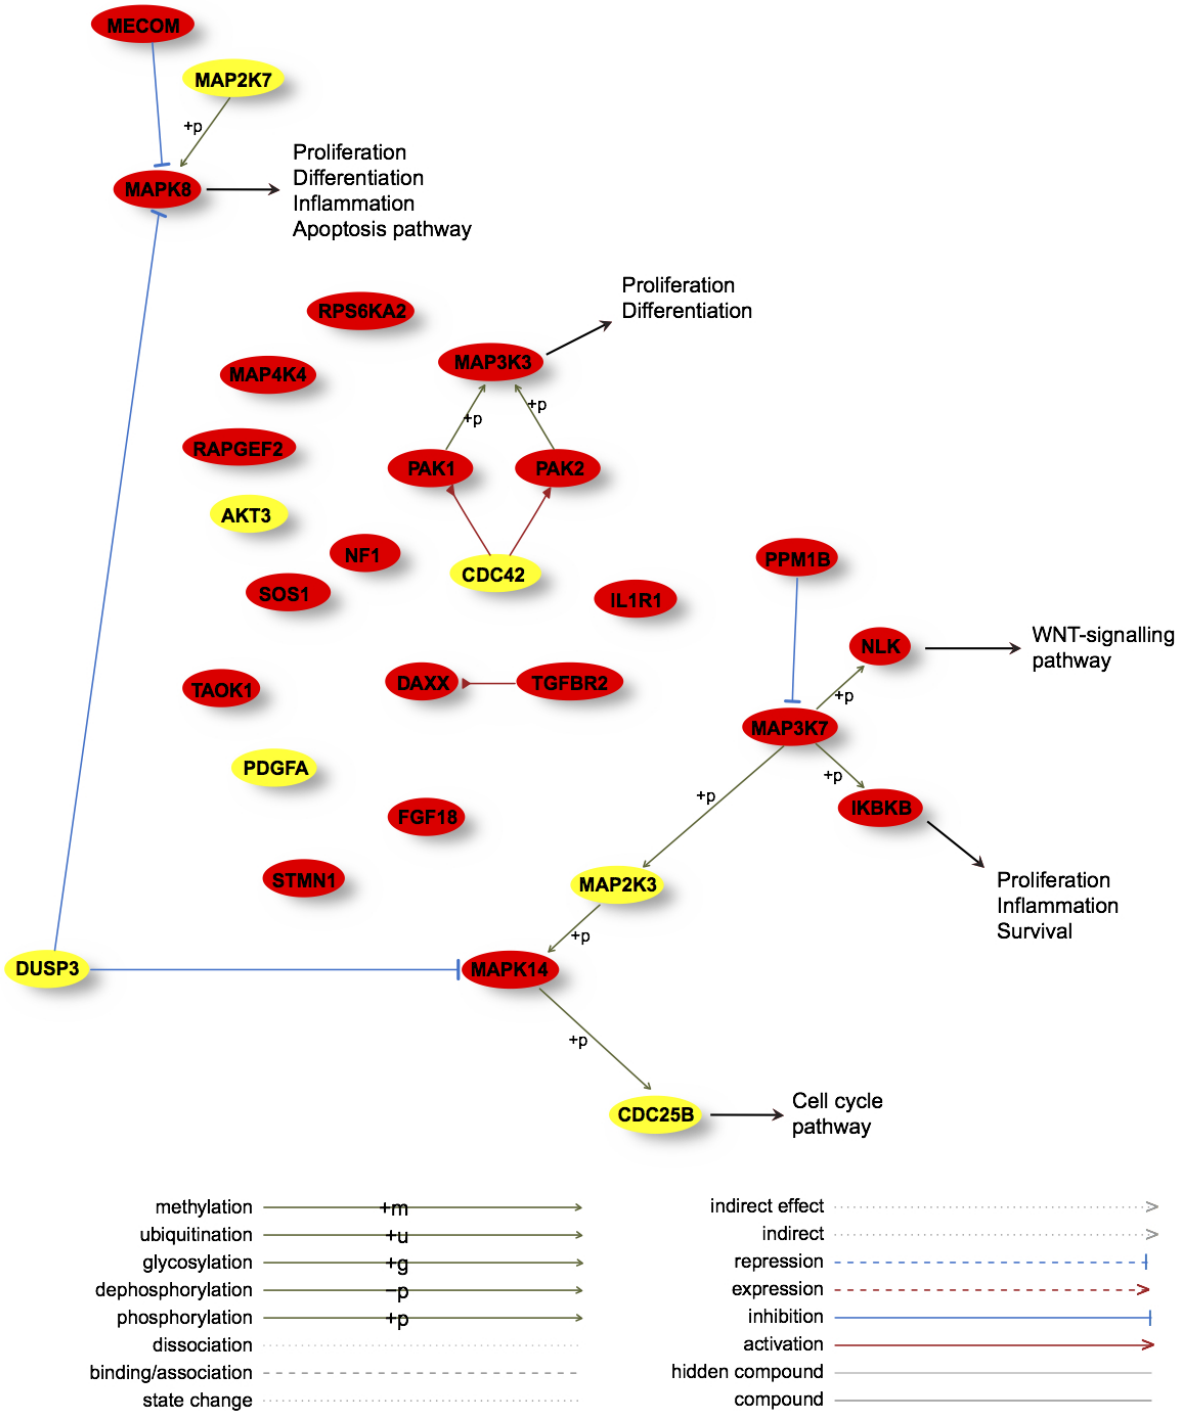

Figure 10.10.: *Interaction patterns within the MAPK-signalling pathway. Gene expressions are visualized by colour-coding with yellow representing up-regulation and red representing down-regulation of the corresponding gene in WISP1 depleted chondrocytes compared to scrambled control assays. Different interactions types are explained in the legend.*

10.2.3. Gene regulations important for cartilage homeostasis

Beside gene regulations, which can be directly linked to apoptosis, investigation of the data sets identified also a cluster of differentially expressed genes important for cartilage homeostasis. This involves mainly gene regulations important for ECM maintenance and replacement as well as regulations that may affect the chondrocyte phenotype. Therefore, all gene regulations were observed without the previous used AFFX cut-off, but with high attention to the logFC and the corresponding adjusted p-value. The heat map below (Fig. 10.11) illustrates this cluster by colour-coding in all chondrocyte samples. The first five columns of this heat map reflect regulations in the control samples and the following five columns the corresponding gene regulation after the WISP1 down-regulation. Affected genes are listed in alphabetical order and genes with regulations of more than one probe set were reduced to the probe set with the highest logFC.

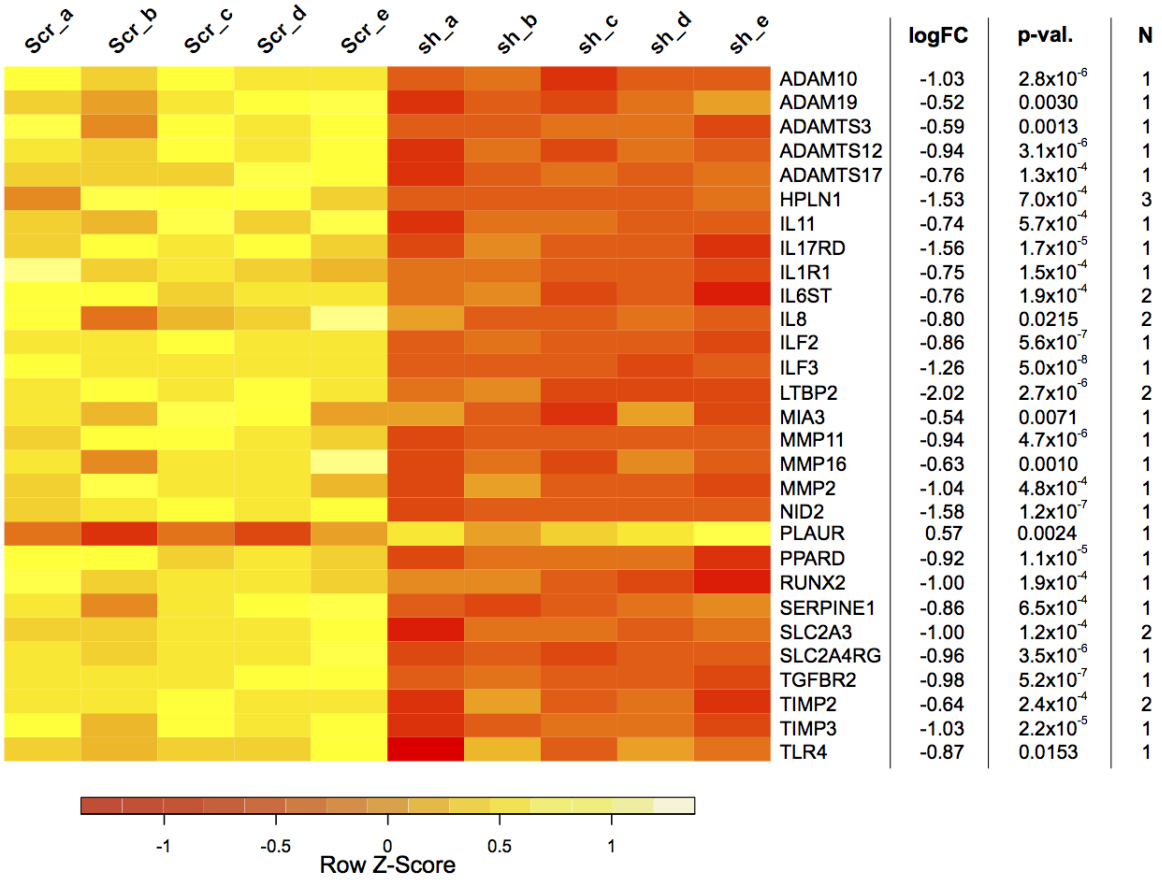

Figure 10.11.: *Heat map of gene regulations important for cartilage homeostasis. Levels of gene expression are visualized by colour-coding with white representing high expression, over yellow and orange as medium expression and red representing low expression of the corresponding probe set. Values are normalized by rows (Z-score). Gene names are aligned beside the rows, with additional information regarding degree of regulation (logFC), the corresponding p-value and the number of regulated probe sets. The highest regulated probe set was chosen for visualization, since more than one regulated probe set was detected. Sample names are presented over each column Scr=scrambled control sample, sh=WISP1 down-regulated sample, logFC=logarithmic fold change, p-val.=adjusted p-value.*

10.2.4. Reevaluation by semi-quantitative RT-PCR

The results of differential gene regulation, obtained during array analysis, were reevaluated by semi-quantitative RT-PCR and confirmed with densitometric analysis of the corresponding gel bands. Amongst all regulated genes, eleven were chosen for reevaluation due to their high fold change (logFC) and functional properties that may be potentially relevant during apoptosis or in consideration to their linkage concerning interactions with the ECM (Tab. 10.8).

Table 10.8.: *Selection of genes for reevaluation. Left to right: Probe set IDs, gene symbols, gene names, degree of regulation (logFC) and p-value. Genes are listed alphabetically according to their descendent statistical score as more than one probe set is regulated.*

Reevaluation by RT-PCR was accomplished with the same RNA samples, which were previously used for the microarray analysis. Eleven gene products could be confirmed according to the microarray analysis (Fig. 10.12; Tab. 10.9). MDM2 with logFC of -0.74 is located to detection limit and thus could not statistically confirmed.

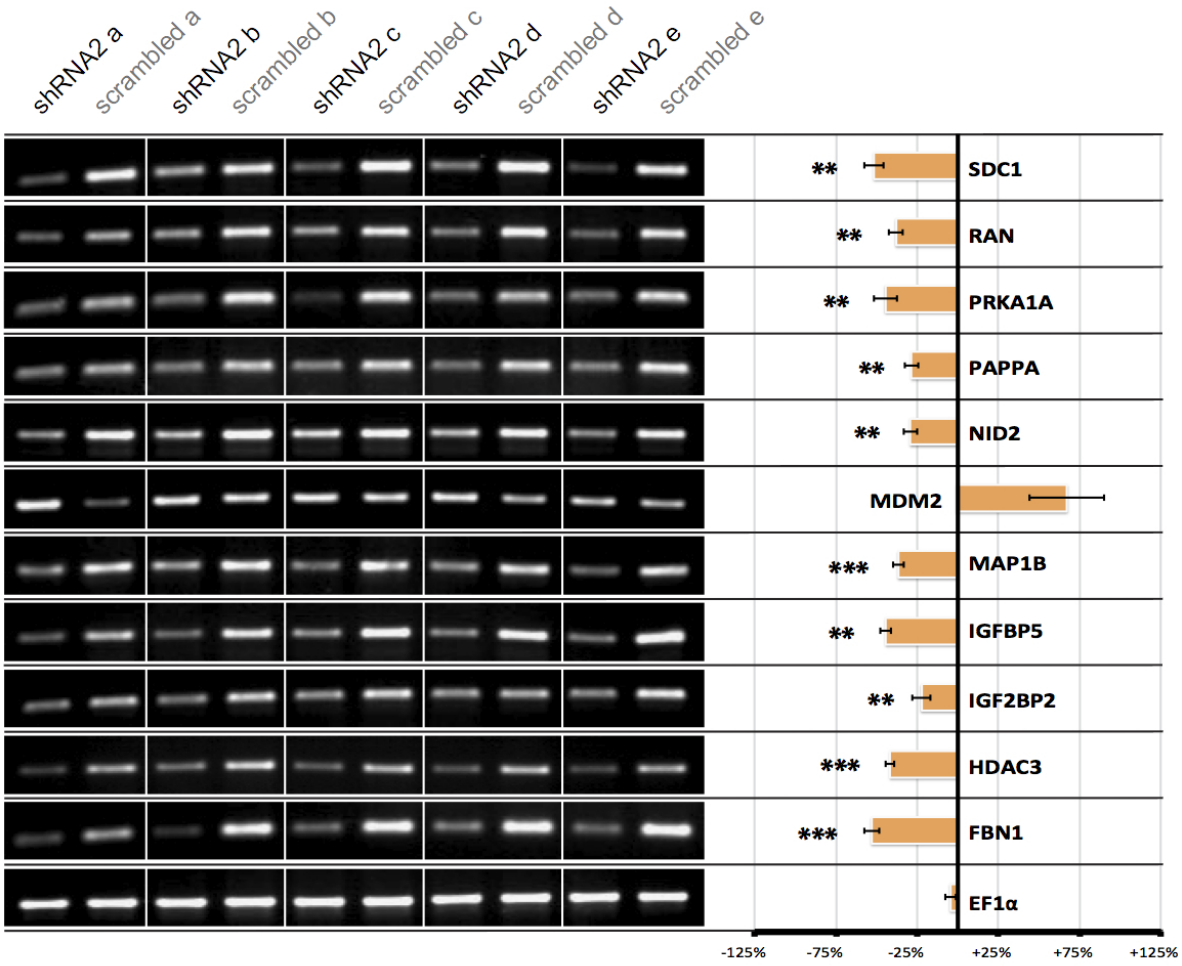

Figure 10.12.: *Reevaluation of selected genes after WISP1 down-regulation in Tc28a2 chondrocytes. In all RNA samples, previously used for microarray hybridization, RT-PCR reactions of selected genes were performed. All inspected genes show an expected regulation according the previously ascertained logFC value. The mRNA levels of the housekeeping gene EF1α were used as internal controls. Densitometric analysis of the corresponding gel bands confirmed the RT-PCR findings. Displayed is the mean of densitometric measures, with the %SEM indicating error bars.*

CHAPTER
ELEVEN

RECOMBINANT PROTEIN PRODUCTION

11.1. Proof-reading PCR and cloning procedures of WISP1-T1, -T2 and WISP2

Full-length cDNA plasmid sequences of WISP1-T1, WISP1-T2 and WISP2, diluted 1:10,1:100 and 1:1000 in HPLC water, were amplified with the Pfx50^{TM} DNA Polymerase and subsequently verified by agarose gel electrophoresis. Figure 11.1 (A) reflects the proof-reading PCR outcome of the WISP1-T1 amplification under exposure to UV-light. All three dilutions show a considerable band of the expected size of 1103bp. The purest PCR product, the 1:1000 dilution in the case of WISP1-T1, was used for the TOPO®cloning amplification. Six putative WISP1-T1 TOPO®clones were selected and plasmid DNA was restricted with specific endonucleases to separate insert and vector DNA. Subsequently, gel electrophoresis (B) exhibit plasmid DNA of five clones (1,2,3,5 and 6,) with the expected WISP1-T1 insert size of 1103bp and plasmid DNA of one clone (4), which contained only unrestricted vector DNA. Insert DNA was verified with sequencing analysis (data not shown) and only confirmed sequences were utilized for cloning into the SF-21 expression vector pBacPAk8. Subsequent to the cloning and purification procedures, restriction of vector DNA and gel electrophoresis visualized the restricted vector and insert DNA. Referring to sequencing analysis of the insert DNA (data not shown), the Fc-tag was cloned N-terminal to the WISP1-T1 sequence into the bBacPAK8 vector. The left region of figure 11.1 (C) illustrates the plasmid DNA bands of six different pBacPAK8 vector containing clones (1a-6a). Plasmid DNA of four clones (1a, 3a, 4a and 5a) exhibit insert DNA of the expected size of WISP1-T1 (1103bp) and the pBacPAk8 vector (5500bp). The right region of figure 11.1 (C) reflects the identical six clones and similar to the previously described findings, the same four clones (1b, 3b, 4b and 5b) contained also the Fc-tag DNA with the expected size of 740bp. Subsequently, the Fc-tag insert DNA was verified with sequencing analysis as well, the expression vector was ready to use for the infection of the SF-21 cell line. Proof-reading PCR and cloning procedures of WISP1-T2 and WISP2 were performed analogous to WISP1-T1 (data not shown) and both were not used until appropriate base pare progression via sequencing analysis could be confirmed (data not shown).

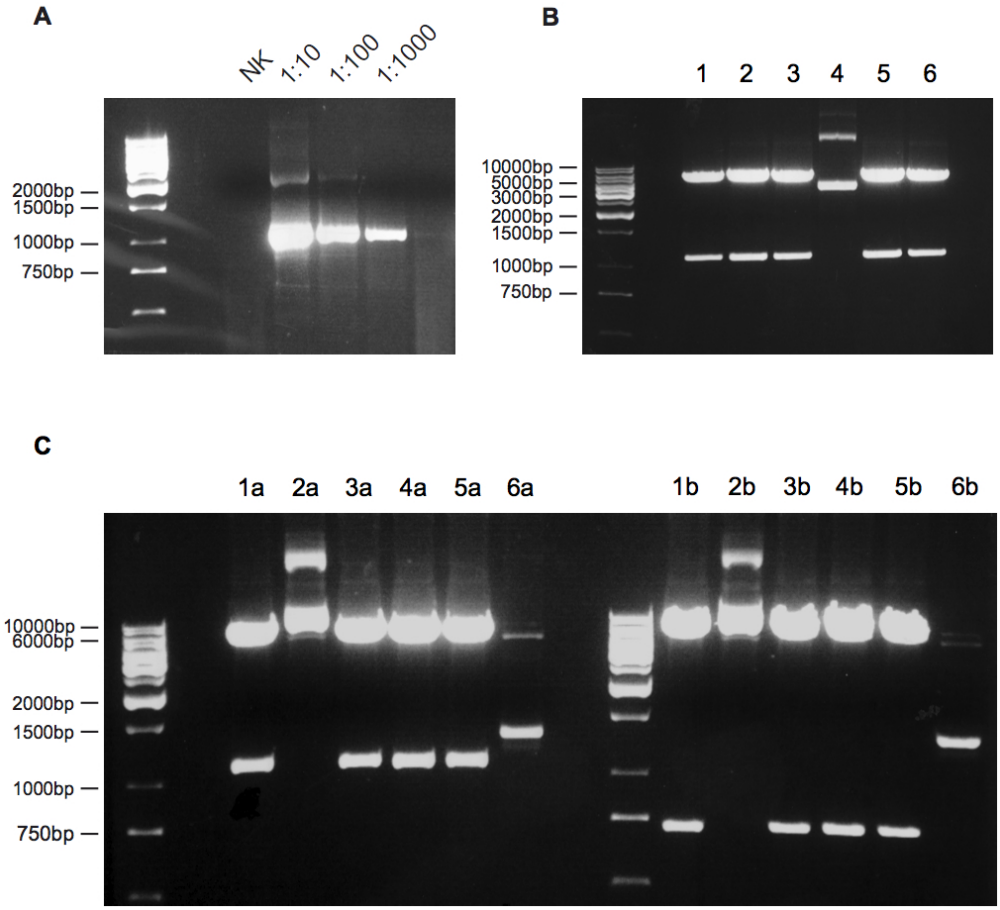

Figure 11.1.: *Proof-reading PCR and cloning procedures of WISP1-T1. (A) Proof reading PCR: three different concentrations of WISP1-T1 full-length cDNA sequence were amplified and visualized via gel electrophoresis. (B) TOPO® cloning: plasmid DNA of five clones (1,2,3,5 and 6,) show the expected WISP1-T1 insert size of 1103bp and plasmid DNA of one clone (4) contained only unrestricted vector DNA. (C) pBacPAK8 vector cloning: four clones (1a, 3a, 4a and 5a) exhibit insert DNA of the expected size of WISP1-T1 (1103bp) and the pBacPAk8 vector (5500bp). Additional, identical clones (1b, 3b, 4b and 5b) contained the Fc-tag DNA with the expected size of 740bp.*

11.2. Recombinant WISP1-T1, -T2 and WISP2 expression

The transfer vector pBacPAK8, containing the inserts of WISP1-T1/Fc-tag, WISP1/T2-Fc-tag or WISP2/Fc-tag, and an additional expression vector were co-transfected into SF-21 cells. Figure 11.2 shows the western blot findings, performed with a primary antibody against the Fc-tag. The upper region (A) reflects the different virus amplification steps, exemplarily for WISP1-T1. The virus amplification comprised p0 (six days after transfection), p1 based on p0 concentrations of 1:10, 1:100, 1:000 (seven days after retransfection) and p2 based on p1 concentrations of 1:25, 1:62.5 and 1:500 (seven days after reretransfection).

Autoradiography visualized two different protein bands per lane with the primary antibody against the Fc-tag. Only the lower one corresponds to the expected size of 67kd for WISP-T1/Fc-Tag. It was not possible to detect rWISP1-T1 in the p0 virus stock. The p1 virus stocks, in contrast, reflected a slight increase in the amount of secreted rWISP1-T1 protein and the p2 virus stock confirmed the virus amplification with an increase of rWISP1-T1. After virus amplification, three $150cm^2$ cell culture flasks were infected with 200μl p2 virus stock.

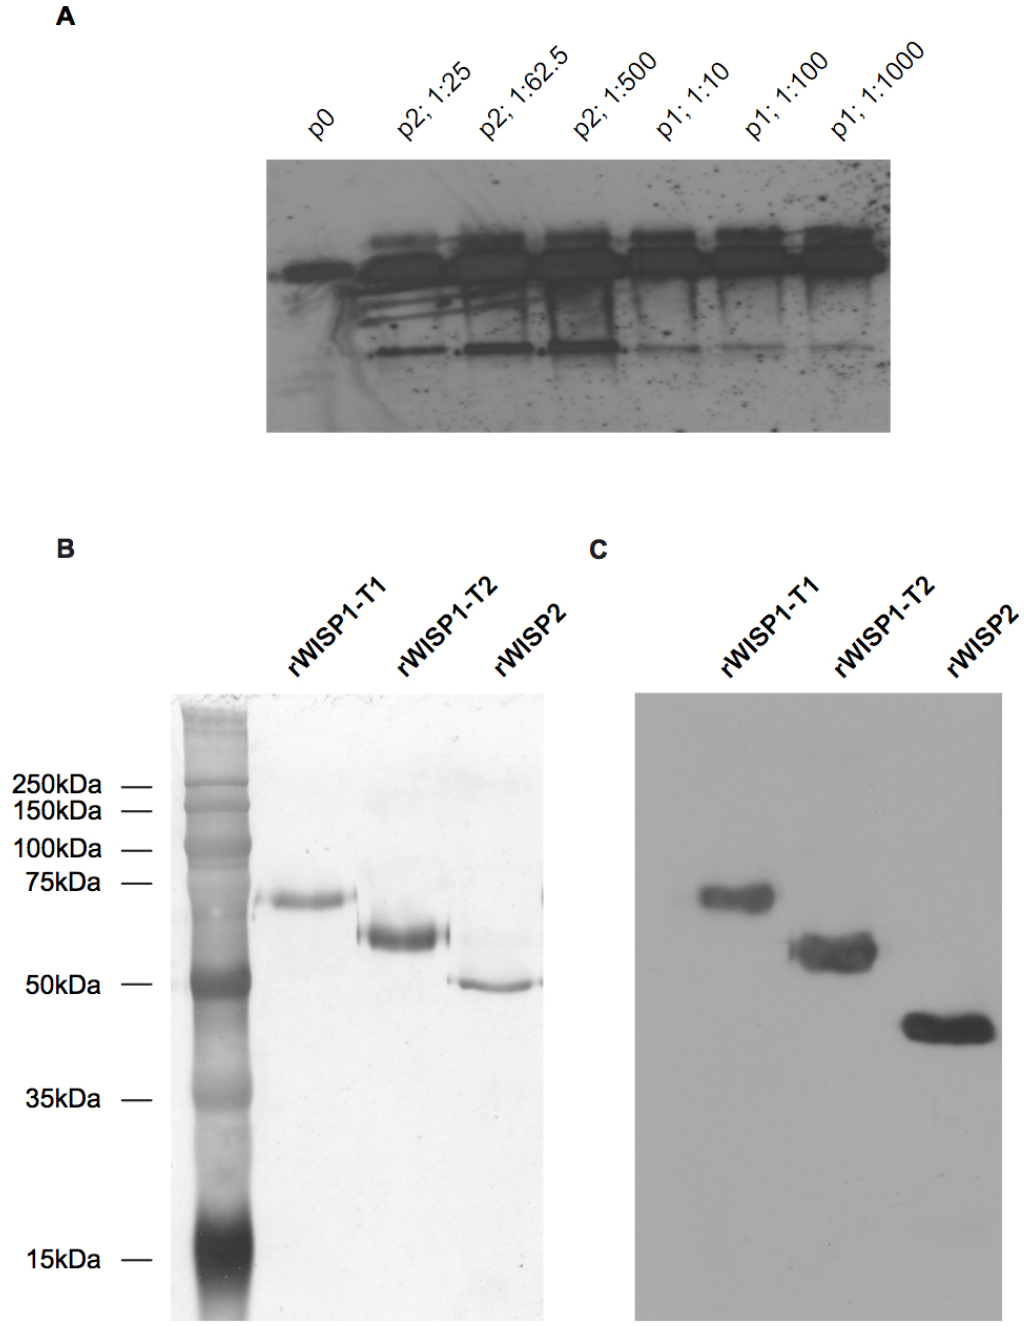

Figure 11.2.: *Western blotting and silver staining of rWISP1-T1, -T2 and rWISP2. (A) Western blot picture of virus amplification p0 (six days after transfection), p1 based on p0 concentrations of 1:10, 1:100, 1:000 (seven days after retransfection) and p2 based on p1 concentrations of 1:25, 1:62.5 and 1:500 (seven days after re-retransfection). The lower detected protein band corresponds with the expected size of 67kd for WISP-T1/Fc-Tag. (B) silver staining after expression and purification of rWISP1-T1, -T2 and rWISP2. Single protein bands of the expected size of 67kDa (rWISP1-T1), 57kDa (rWISP1-T2) and 53kDa (WISP2) were detectable. (C) Confirming of the same proteins with western blotting revealed protein bands in identical size and purity.*

Approximately seven days after transfection, cell supernatant yielded between 100 and 400μg of the respective (r)protein. Subsequently, 250μg of each protein was loaded onto a SDS page and proximate silver staining procedures (B) and western blotting analysis (C) revealed single protein bands of expected size and purity. rWISP1-T1 (67kDa), the largest of the three proteins, was detectable in the first lane of the blotting membrane. The 10kDa smaller second transcript variant was exhibit with a size of 57kDa in the second lane of both illustrations (B and C) and WISP2 (53kDa) in the third lane.

11.3. Functional testing of rWISP1-T1, -T2 and WISP2

The effectiveness of rWISP1-T1, -T2 and rWISP2 proteins was verified by treatment of Tc28a2 cells. With this experiment, it was possible to confirm a self-regulation of all three produced rWISP proteins in this chondrocyte cell line. To improve the function of rWISP1-T1 and -T2, the endogenous amount of both proteins were down-regulated. Three days after the transduction procedure was performed, 500ng rWISP1-T1 (pH: 7.0) was added into serum less medium (0%FCS) of the shRNA2 transduced Tc28a2 cells for 24h. Simultaneous, a second shRNA2 assay was treated with 500ng rWISP1-T2 (pH: 7.0). A scrambled control was used to compare the WISP1-T1 and -T2 mRNA levels with those of the knock-down experiments. Additionally, GFP was used first, as a positive control for measuring transfection and transduction efficiency and second, for comparison of the different WISP1-T1 and -T2 mRNA levels. Figure 11.3 illustrates an example of the RT-PCR analyses of the isolated mRNA from the fourth day after transduction. The mRNA level of both WISP1 transcript variants were remarkably down-regulated compared with the scrambled and GFP controls. In contrast, shRNA2-transduced cells, treated with 500ng rWISP1-T1, show an intensive increase of its own mRNA level during the knock-down experiments. The same findings could be observed by the application of the second recombinant transcript variant. 24h after treatment with 500ng rWISP1-T2, down-regulation induced by shRNA2 was compensated by an intensive increase in its own mRNA production. Total mRNA of seven independent experiments was isolated on day four after transduction and is illustrated by the densitometric analysis in table 11.1.

No expression of WISP2 was observable in 90-100% confluent Tc28a2 cells under normal cell culture conditions (Fig. 8.1, C). Therefore, the effectiveness of rWISP2 could be verified by application of the recombinant protein under standard cultivation procedures. Prior to the protein treatment cells were cultivated with serum less medium (0%FCS) for 24h and subsequently treated with 500ng rWISP2 for additional 24h. After isolation of total RNA, RT-PCR analyses revealed an intensive increase in the endogenous amount of the mRNA level of WISP2. These findings were confirmed by replicates (n=5) and the respective densitometric analysis (Fig. 11.4; Tab. 11.2).

11.4. rWISP1-T1 and -T2 treatment of Tc28a2 chondrocytes after WISP1 gene-silencing

Effects of the rWISP1-T1 and -T2 proteins were determined by application of these proteins to Tc28a2 chondrocytes after WISP1 gene-silencing. Previously, both recombinant transcript variants were verified of expected size and purity using western blot analysis and silver staining procedures (Fig. 11.2). According to the transduction, 500ng rWISP1-T1 (pH: 7.0) was added into 3ml medium of the shRNA2 transduced Tc28a2 cells. Simultaneous, one shRNA2 assay contained 500ng rWISP1-T2 (pH: 7.0) and a third shRNA2 transduced assay comprised 500ng of each recombinant produced transcript variants. The applications of (r)proteins were con-

tinued every two days with the addition of fresh medium to the cells. Supplemental controls were estimated at the same time. The first control was a pure shRNA2 transduced assay to compare optical differences between recombinant treated and untreated WISP1 knock-down cells. A scrambled control served as a negative control for effects of the lentivirus system and a GFP control was needed for validation of the transduction efficiency. Figure 11.5 illustrates the described assays following day 5 to day 8 after transduction of the cells. These four days were selected, because optical differences between shRNA2 transduced Tc28a2 cells and the scrambled control assays were clearly observable during the initiated time series. There were no optical differences detectable between pure shRNA2 transduced cells (A1-D1) and those who contained additional rWISP1-T1 (A2-D2), rWISP1-T2 (A3-D3) or both recombinant produced transcript variants (A4-B4) on each monitored day. The scrambled control shows normal proliferation during these four days (A5-D5) and the GFP control revealed an expected transduction efficiency under exposure to UV-light (A6-D6).

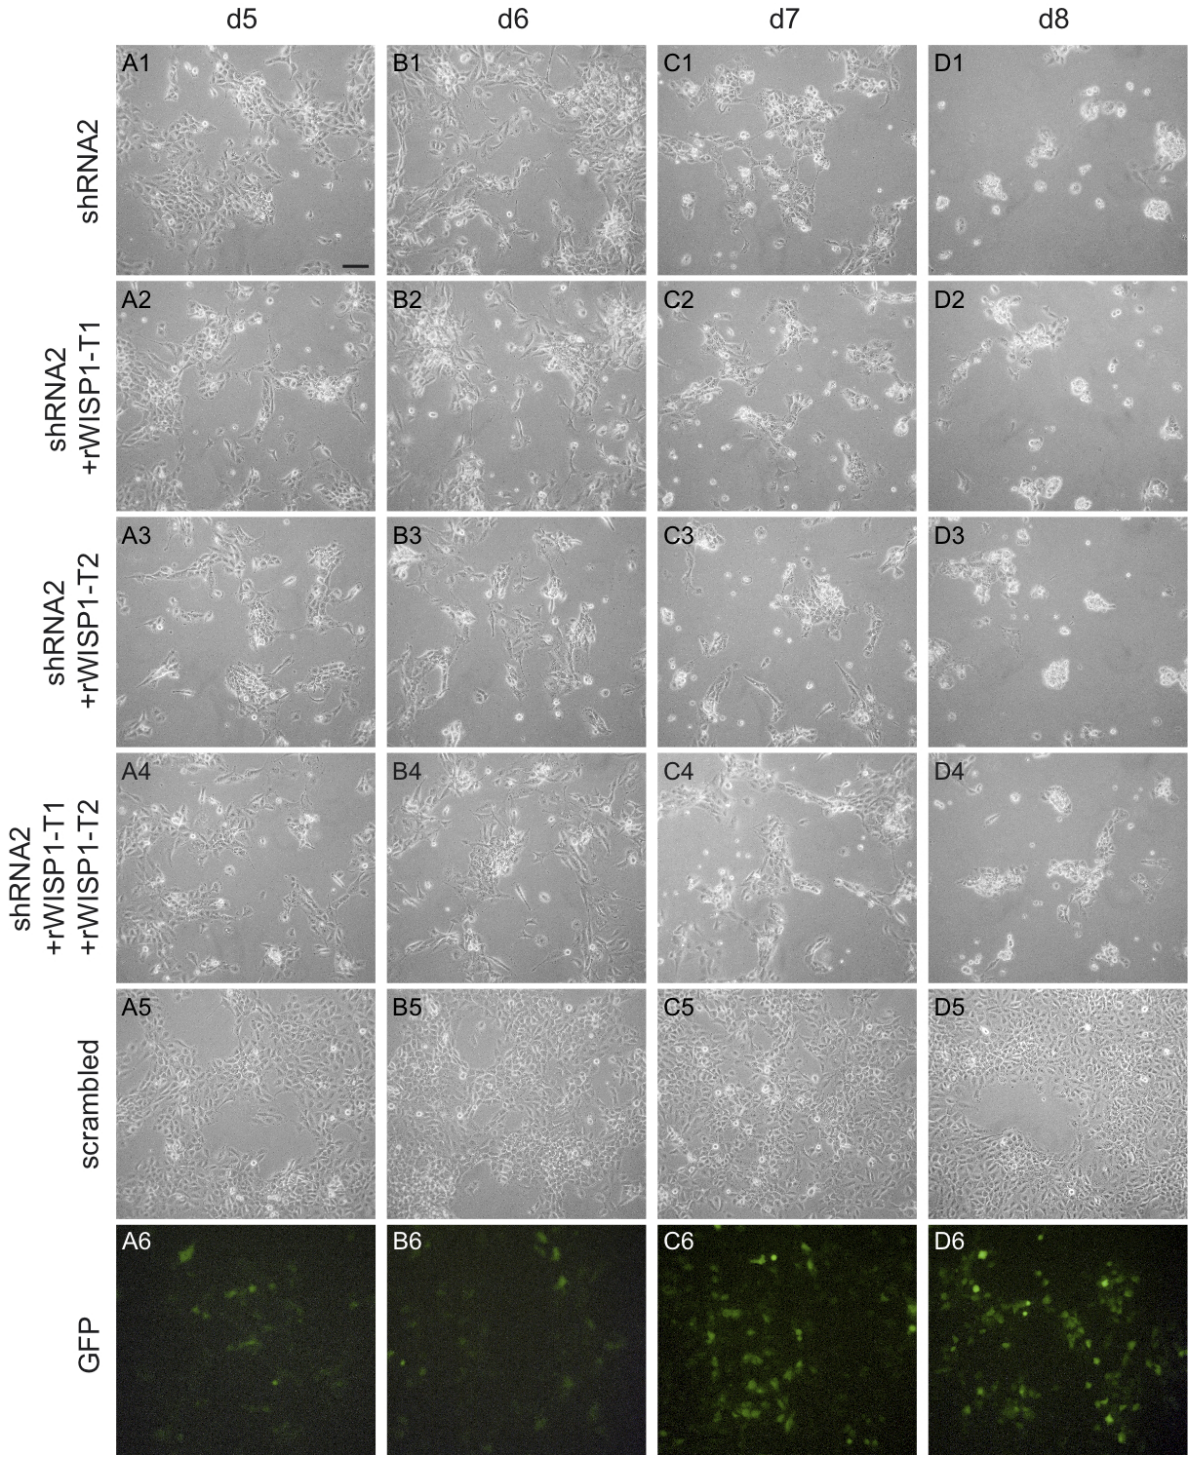

Figure 11.5.: *Treatment with rWISP1-T1 and -T2 of WISP1 down-regulated chondrocytes. Column 1-4 illustrates cell death of WISP1 within one week after the transduction was performed. Protein treatment with rWISP1-T1 (A2-D2), rWISP1-T2 (A3-D3) and both recombinant proteins (A4-D4) show no effect concerning cell survival or decelerated cell death. Control samples (scrambled and GFP) display expected proliferation and successful transduction of the chondrocyte cell line Tc28a2. Scale bar=*$100\mu m$.

CHAPTER

TWELVE

CONTINUATIVE EXPERIMENTS

12.1. Apoptosis detection with FLICA (fluorochrome inhibitor of caspase) in Tc28a2 chondrocytes

The FLICA assay was established to distinguish between apoptotic and healthy cells within the same cell population. Tc28a2 chondrocytes were seeded onto cover slips and subsequently treated with 100μM zolendronate for 72h. The apoptosis induction via zolendronate was confirmed by immuno-cytochemical staining procedures with sulforhodamine labelled FLICA. Figure 12.1 illustrates the different fluorescence marker under exposure to UV-light. Hoechst3334 stained all present nuclei with bright blue fluorescence (A and D), while the sulforhodamine FLICA stain, detected a broad range of active caspases. Zolendronate treated (apoptotic cells) exhibited a higher amount of active caspases (B) compared to untreated control cells (E). Both fluorescence stainings could be merged to quantify cells of respective active caspases (C and F).

12.2. Cytochrome c staining in hMSCs

When internal pro-apoptotic stimuli induce breakdown of the mitochondria, cytochrome c is released into the cytosol where it leads to activation of caspases and thus triggers apoptosis. Therefore, cytochrome c staining will be used to detect internal apoptosis stimuli via cytochrome c release. Bone marrow derived hMSCs were seeded on cover slips until they reached 50-60% confluence. Figure 12.2 shows the subsequent immune-cytochemical staining of hMSCs with a primary, fluorescence labelled antibody against cytochrome c (A-D) and the respective negative control (E-H). Nuclei of all cells were counterstained with DAPI (A and E) for displaying the whole cell population under exposure to UV-light. Because cytochrome c is located in the outer membrane of the mitochondria in viable, healthy cells, a second counterstain with MitoTracker® Red was performed to visualize the mitochondria of each cell (B and F). A FITC labelled secondary antibody against the primary cytochrome c detecting antibody, stained the respective protein with bright green fluorescence (C). An overlay of all stainings confirmed the cytochrome c location in the mitochondria of the cells (D). A negative control passed both counterstains and the incubation with the FITC labelled secondary antibody. No staining was observable in the absence of the primary antibody against cytochrome c (G and H).

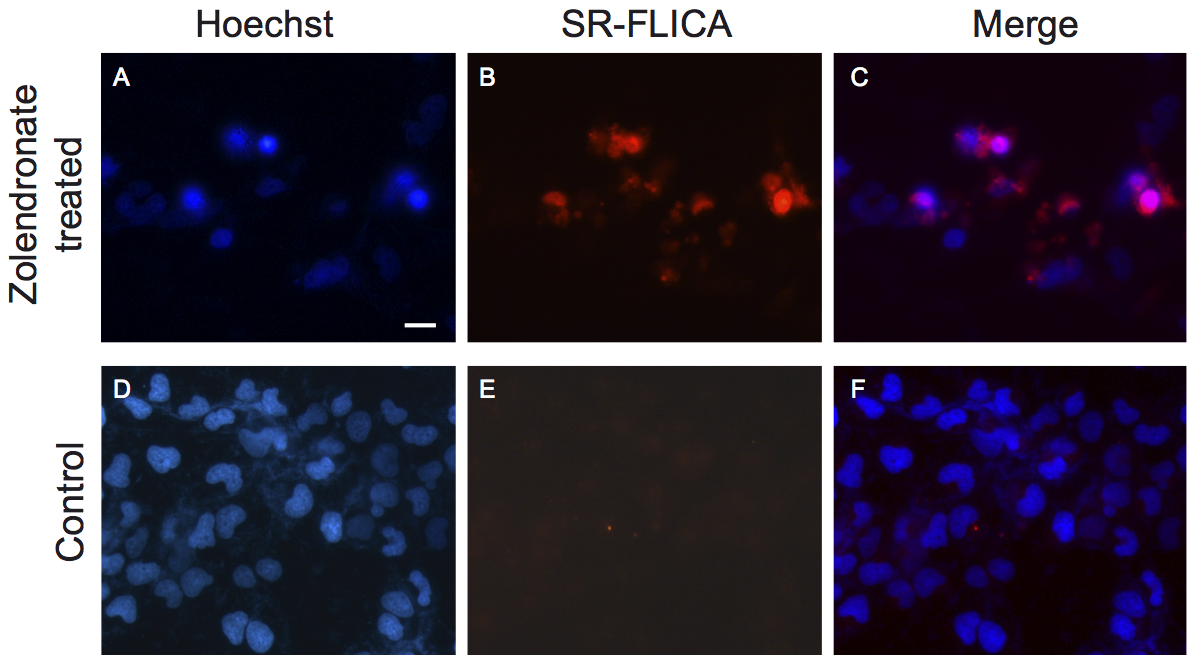

Figure 12.1.: *Detection of apoptotic Tc28a2 chondrocytes with FLICA. Fluorescence microscopy uncovered active caspases in zolendronate treated chondrocytes compared to non-zolendronate treated control cells. (A) Labelling of zolendronate treated cells with nucleus counterstain Hoechst, (B) staining with FLICA (sulforhodamine-VAD-FMK poly caspase inhibitor) reagent and the corresponding non zolendronate treated control saples (D, E). An overlay of both stainings is illustrated in (C) for zondronate treated and in (F) for untreated control cells. Scale bar=*$20\mu m$.

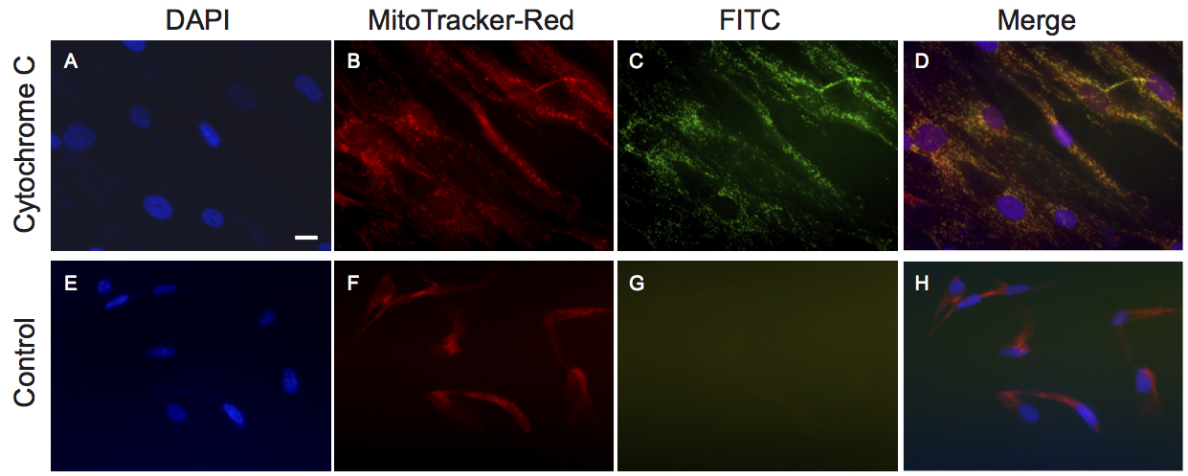

Figure 12.2.: *Cytochrome c immuno-staining of hMSCs. Cells were labelled with the nuclei counterstain DAPI (A, E), the mitochondria marker MitoTracker® Red (B, F) and antibodies against cytochrome c. The negative control (E-H) contained all described components, except the primary antibody against cytochrome c. Scale bar=*$20\mu m$.

12.3. P53 staining in hMSCs

The location of the tumour suppressor p53 in apoptotic hMSCs and chondrocytes will be visualized to verify one possible mechanism of apoptosis induction. Previously, hMSCs were seeded onto cover slips until they reached 50-60% confluence. Subsequent immuno-cytochemical staining with a primary antibody against p53 is illustrated in figure 12.3. DAPI was used as a counterstain to identify all nuclei of determined cells (A). A FITC labelled, secondary antibody visualized the tumour protein p53 within the cytoplasm of the cells (B and C), while the negative control remained widely unstained (E and F).

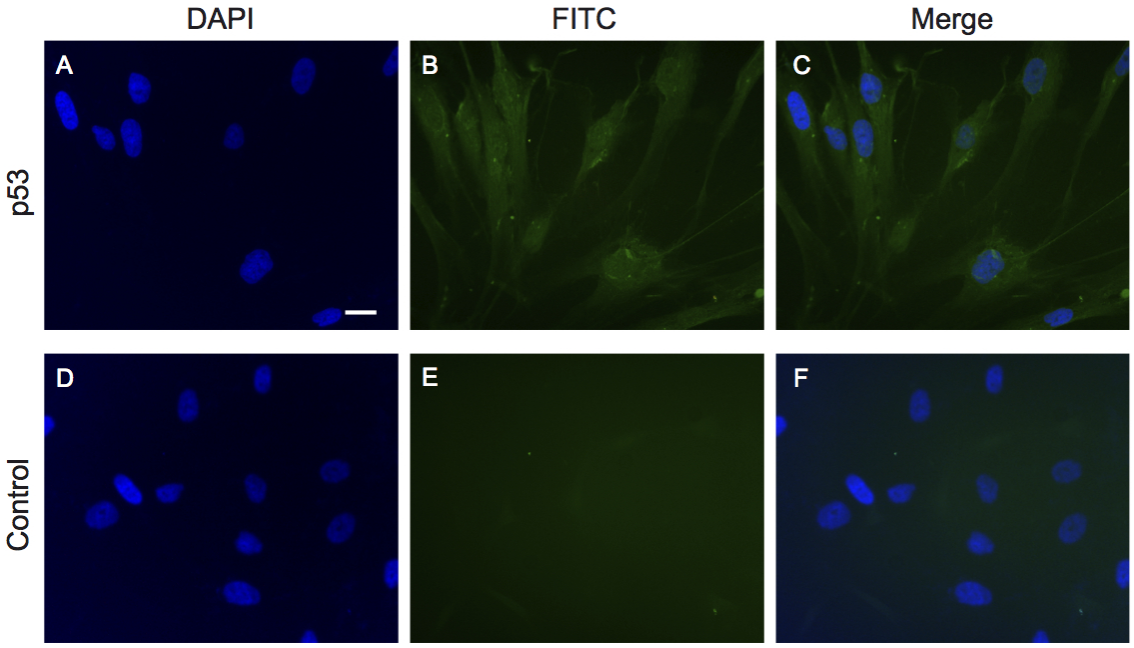

Figure 12.3.: *p53 immuno-staining in hMSCs. Cells were labelled with the nuclei counterstain DAPI (A, D). A FITC labelled, secondary antibody visualized the tumour protein p53 in the cytoplasm (B), while the negative control remained widely unstained (E). Scale bar=*$20\mu m$.

Discussion

CHAPTER
THIRTEEN

NATIVE EXPRESSION OF WISP1 AND WISP2 IN MUSCULOSKELETAL CELLS

Within the last decades, CCN protein family members have been identified as important ECM-associated, multifunctional regulators with significance in skeletal development and fracture repair (Hadjiargyrou et al. 2000; Nakata et al. 2002; O'Brien and Lau 1992). Previous studies of our working group already confirmed the differential expression of CYR61/CCN1, CTGF/CCN2, WISP2/CCN5 and WISP3/CCN6 during the differentiation of hMSCs in osteoblasts, chondrocytes or adipocytes (Schuetze et al. 2005), therefore indicating a prominent role during lineage progression. This investigation was supported by findings of French et al. (2004), who demonstrated the role of WISP1 as an osteogenic potentiating factor, which additionally represses the chondrocytic differentiation of MSCs. Apart from functional investigations of WISP1 within the musculoskeletal system, independent working groups depicted this protein as an important cellular survival factor. Thereby, it promotes cell growth and tumourigenesis (Su et al. 2002; Venkatesan et al. 2010). Considering the aforementioned examinations, several hypotheses were designed, established and investigated during this PhD thesis to provide a detailed view on WISP1-signalling in cells connected to the musculoskeletal system and its influence on cell survival and apoptosis.

The first hypothesis comprised the presumption that a natural expression of WISP1 (both transcript variants) and WISP2 exists in a variety of musculoskeletal cell types, i.e. primary hMSCs, osteoblasts and chondrocytes. The initial experiments confirmed the native expression of WISP1 in primary hMSCs as well as in different chondrocyte, osteosarcoma and osteoblast cell lines. Beside the expression of full-length WISP1 (-T1), we were able to detect the expression of a WISP1 isoform (-T2), which lacks the VWC domain, in all corresponding cell types as well. This isoform was first described by Yanagita et al. (2007) as naturally expressed in primary rabbit growth cartilage chondrocytes.

In contrast, the expression of WISP2 could not be confirmed. None of the examined cell lines displayed a continiously native expression of this protein. Accordingly, the expression of WISP2 in primary hMSCs seemed to be donor dependent and ranged from no expression, over little to an adequate expression. Neither age of donors nor their genders seem to be correlated with WISP2 expression. Due to privacy protection of donors, little is known about live and behaviour of the stem cell donors. Thus, it is difficult to explain a differential protein expression between donors, because it is not possible to exclude relevant medication or diseases, which may effect protein expression in such a case.

Subsequent to a successful validation of the natural expression of WISP1 in different cell types of the musculoskeletal system, the next approach included experiments to examine how cells can be affected by corresponding gene-silencing.

CHAPTER
FOURTEEN

WISP1 GENE-SILENCING

14.1. WISP1 gene-silencing leads to cell death in a variety of musculoskeletal cells

For the subsequent designed microarray comparisons of WISP1 down-regulated and control cells, it is important to apply specific shRNA constructs to engage target mRNAs of both detected transcript variants. Due to the fact that all CCN family members share several conserved sequence homologies, targeting a specific member by shRNA hairpins, like WISP1, is a difficult task. Therefore, experiments were confirmed with a second shRNA construct to exclude the observations of so called "off-target effects". These effects will occur if an assumed specific shRNA hairpin directly alters other genes. Appropriate shRNA constructs were selected due to their ability to target different domains existing in WISP1-T1 and -T2 (shRNA2 - TSP domain; shRNA5 - CT domain). A successful down-regulated expression of WISP1-T1 and -T2 was achieved in the chondrocyte cell line Tc28a2. Conspicuously, immediately after successful transduction, WISP1 depleted chondrocytes displayed optical differences in comparison to their control samples with the consequence of cell death. The application of shRNA5 onto the target cells induced a reduction of WISP1-T1, which was however not as intensive as the effect observed with shRNA2. This was confirmed by RT-PCR and the incidental difference in cell characteristics was comparably less acute, correspondingly. Off target effects can be excluded as both utilized shRNA constructs resulted in a down-regulation of WISP1-T1 and -T2 expression with subsequent cell floating. Although WISP1 shares 32% amino acid sequence identity with WISP3, additional RT-PCR analysis verified an unaffected expression of WISP3 in all samples compared to untreated cells (data not shown). Based on these methodically considerations, results of the gene-silencing studies are reliable and support the hypothesis of WISP1 as an essential survival factor for chondrocytes.

Further experiments, all performed with both effective shRNA constructs (shRNA2 and -5) and control constructs (scrambled, GFP and pure vector) were accomplished to investigate optical alterations after loss of WISP1 in several selected cell lines. To cover many areas of the musculoskeletal system, a second human chondrocyte cell line (C28I2), one human osteoblast cell line (hFOB) and two immortalized hMSC cell lines (hMSC-TERT4 and hMSC-TERT20) were chosen. Surprisingly, WISP1 seems to act as a general survival factor within the musculoskeletal system, due to the fact that every cell line in our investigation wasn't able to survive after down-regulation of WISP1. Both appropriated shRNA constructs revealed an effective down-regulation of both transcript variants of WISP1, confirmed by subsequent RT-PCR analyses. Similarly to the findings of the WISP1 down-regulation in Tc28a2 chondrocytes, little difference in the effectiveness of both shRNA constructs could be observed. The examined

osteoblast and chondrocyte cell lines displayed delayed optical difference in shRNA5 transduced samples compared to those transduced with shRNA2. In contrast, hMSC-Tert4 and hMSC-Tert20 cells deceases slightly faster after the transduction with the shRNA5 construct compared to the other one. An allocation between a specific shRNA construct and their effectiveness in WISP1 down-regulation could be observed through RT-PCR analyses. Except the chondrocyte cell line C28a2, all remaining cell lines seem to display stronger effects on cell survival by that shRNA construct, which exhibit a slightly increased down-regulation of WISP1-T1. This leads to the suggestion that the full-length variant of WISP1 could be more important for cell survival in majority of the selected cell lines.

In primary cells, both shRNA constructs were effective as well and similar to the immortalized hMSC cell lines shRNA5 displayed slightly more effect in WISP1-T1 down-regulation, which could also be confirmed by altered cell phenotype. Shortly after the effective down-regulation of WISP1 could be confirmed by RT-PCR analyses, cells weren't able to survive. These additional experiments of WISP1 gene-silencing exclude that the observed results are artefacts from a specific cell line and are furthermore the strongest evidence for the importance of WISP1-signalling in the human musculoskeletal system. The effect on cell survival by WISP1 gene-silencing has never been demonstrated in literature and is a novel finding. Therefore, microarray analyses were performed to give new insights in cell signalling concerning cell survival and -death in the enforced absence of WISP1 expression.

CHAPTER

FIFTEEN

WISP1 AND ITS CONNECTION TO CELL SURVIVAL

WISP1 seems to be important for cell survival in human musculoskeletal cells, but how could it affect viability? Several questions arouse concerning WISP1 as an important survival factor in different tissues of the musculoskeletal system. The protein is described as a general survival factor that prevents several cell types for undergoing apoptosis (Su et al. 2002; Venkatesan et al. 2010). Is it possible that WISP1 acts through different survival mechanisms in diverse cell types? Thus, it was very interesting to investigate WISP1-signalling in different cells of the musculoskeletal system. Primary hMSCs and the immortalized chondrocyte cell line Tc28a2 were chosen for this purpose.

Microarray comparisons were designed, shortly after WISP1 down-regulation took place, to exhibit initial effects of apoptotic signalling. Therefore, all samples were first inspected to reflect no optical differences between shRNA treated- and scrambled control cells. Second, all shRNA samples were subsequent validated to reflect a successful down-regulation of WISP1 expression. Raw data of the following gene expression analyses contained no defective or inadequately spotted regions of the chip itself and the quality of all RNA samples was adequate as well. Raw data were normalized by three different methods (Q, RMA, VSN), whereat RMA yielded the best normalization and was used for the following analyses in both cell types. Several differentially expressed genes, detected during the microarray analyses, were successfully validated with technical and biological replicates through RT-PCR, thus confirming the reliability of the microarray results.

15.1. Microarray analysis uncovered initial apoptosis effects in WISP1 down-regulated hMSCs

The term apoptosis was established by the research trio Kerr, Wyllie, and Currie in 1972 to distinguish a morphologically form of cell death, which was associated with normal physiology. In contrast to necrosis, a form of traumatic cell death, apoptosis is a highly conserved cell mechanism that enables metazoans to control their cell numbers in tissues and thus plays a central role in embryonic development and homeostasis (Jacobson et al. 1997; Wyllie et al. 1980). However, only two major apoptotic signalling pathways were classified: the intrinsic mitochondria-mediated pathway and the extrinsic death receptor-induced pathway (Fig. 15.1). Both major cell death pathways are controlled by cysteinyl aspartate-specific proteinases (caspases). This is an evolutionarily conserved family of cell death effector and cytokine-processing enzymes, which mediate apoptotic signals and cleave a multitude of substrates, thereby causing cellular demolition (Green and Reed 1998; Nuñez et al. 1998; Thornberry 1999).

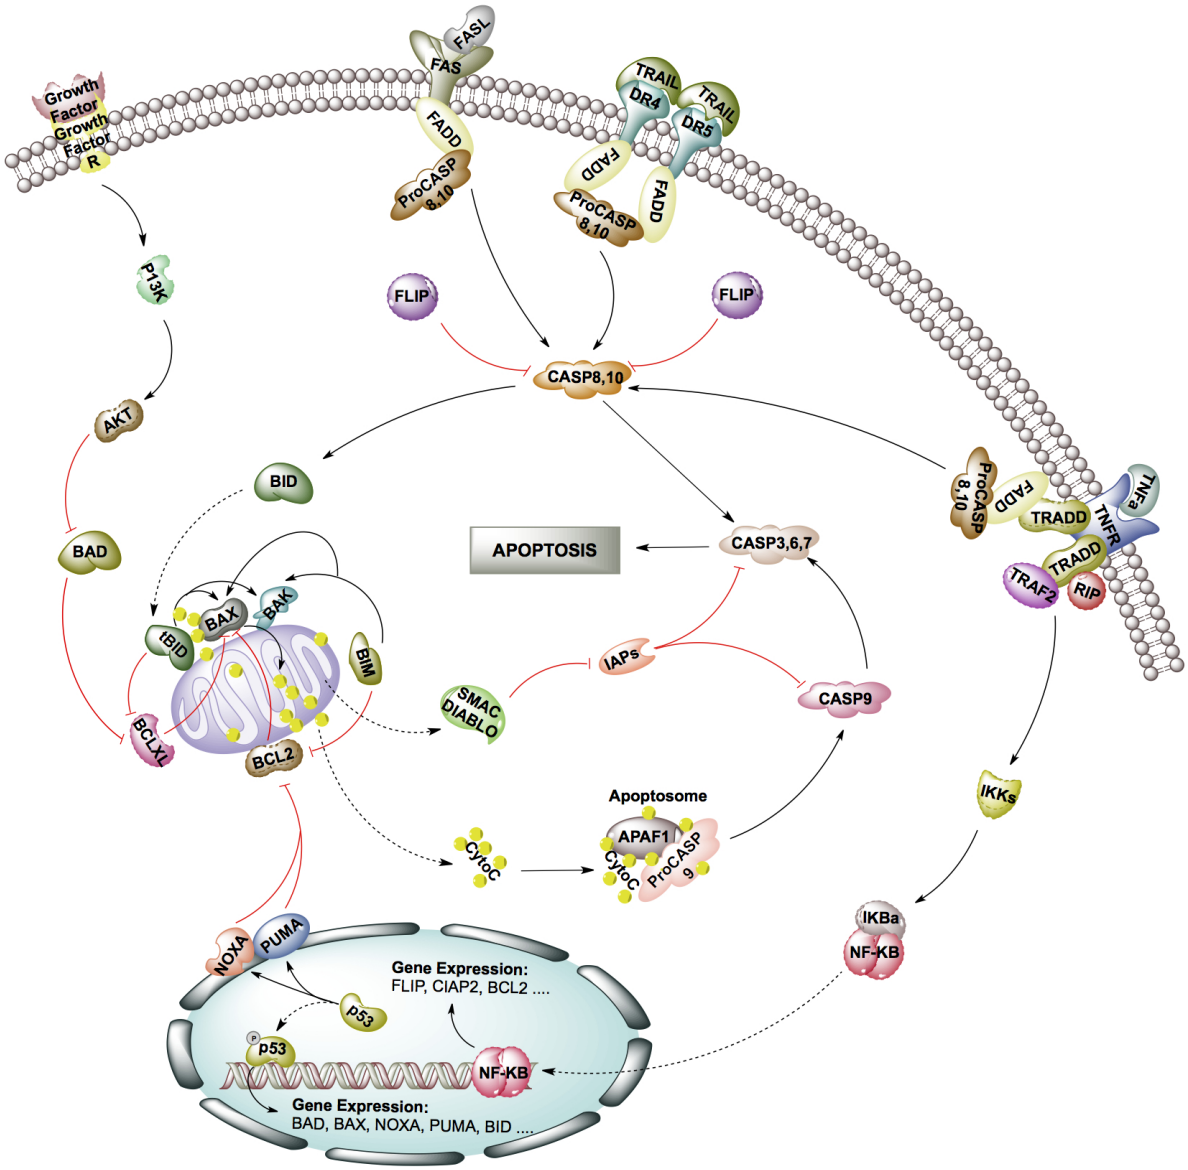

Figure 15.1.: *Extrinsic- and intrinsic-mediated apoptosis induction. Receptor-mediated (extrinsic) apoptosis is initiated by external stimuli like toxins, hormones and cytokines. Cell surface receptors transfer the signalling cascade into the cytosol where the activation of CASP8 and -10 leads to the cleavage of the effector caspases 3 , -6 and -7. Mitochondria-mediated (intrinsic) pathway can be initiated by oxidative stress, UV- or gamma-irradiation, kinase inhibitors and different cytotoxic compounds. Signalling is regulated by BCL2 family members, which lead to CASP9 activation and subsequent cleavage of CASP3, -6 and -7.*

15.1.1. Receptor mediated apoptosis via TRAIL

Genome wide microarray analysis of WISP1 down-regulated primary hMSCs, revealed a cluster of differential expressed genes important for cellular apoptosis induction. In contrast to the examined control samples, WISP1 down-regulation specifically affected genes important for both main apoptosis signalling cascades: the extrinsic- and intrinsic-mediated pathways. One of the most significant differentially expressed genes in this study is the tumor necrosis factor related apoptosis inducing ligand (TRAIL). TRAIL is known as a major cell-death inducing factor, which initiates the extrinsic-mediated apoptosis pathway by binding to its cell surface receptors DR4 and DR5 (Pan et al. 1997; Sheridan et al. 1997; Walczak et al. 1997).

The microarray data confirmed TRAIL-induced apoptosis by showing similarly upregulation of both corresponding death receptors, whereas no evidence for the apoptosis induction via other major death ligands (e.g. FAS ligand) was revealed. Following the extrinsic-mediated apoptosis cascade another key component, the expression of the effector caspase 8, is increased in all WISP1 deficient samples. CASP8 has two main functions during apoptosis. On the one hand, it can cleave downstream effector caspases (CASP3, -6 and -7) leading directly to apoptosis (Boldin et al. 1996). On the other hand, it has the ability to cleave BH3 interacting domain death agonist (BID), a pro-apoptotic member of the BCL2 family. Cleavage of BID generates the truncated active form tBID, which translocate to the mitochondrial membrane and initiates the intrinsic apoptotic pathway (Li et al. 1998; Luo et al. 1998). Accordingly, it was also possible to identify an intensified expression of this linker protein in WISP1 deficient hMSCs.

This study reflects for the first time a correlation between the TRAIL induced apoptosis cascade and WISP1-signalling in human cells. Detection of TRAIL, some of its important binding partners and subsequent signalling proteins is further interesting concerning the question, whether WISP-signalling has implications for anti-tumour strategies. In general, apoptosis induction has become an important approach for the development of new anti-cancer treatments. TRAIL has thereby emerged as one of the most promising apoptosis inducer for death receptor targeted cancer therapy.

In vivo, TRAIL reflects the remarkable feature of selectively inducing apoptosis in tumours without effecting non-transformed cells (Walczak et al. 1999). However, several primary tumour cells show resistance to TRAIL-induced apoptosis and various mechanisms have been suggested to evoke this resistance (Wang 2008). Development of chemotherapeutics or other biological agents are important to sensitize primary tumour cells to TRAIL induced apoptosis. Detection of proteins involved in this signalling cascades, like WISP1, are essential parts and constitute a premise for these strategies.

Beside the importance of TRAIL concerning anti-tumour strategies, its signalling is also suggested to be important for bone resorption and the osteoclastogenesisis of human peripheral blood cells (Zauli et al. 2004). Therefore, TRAIL has the ability to bind a third receptor, which is called osteoprotegerin (OPG) (Emery et al. 1998). This is one of the known decoy receptors, which protect cells against TRAIL-induced apoptotic signalling (Emery et al. 1998; Sheridan et al. 1997). However, main function of OPG is the regulation of osteoclastogenesis (Tsuda et al. 1997).

One key factor for mediating osteoclastogenesis is the osteoclast differentiation factor RANKL (Yasuda et al. 1998). This protein has also the ability to bind OPG. By competing with TRAIL for OPG binding, RANKL may be enforced to bind its second receptor activator of nuclear factor kappa B (RANK). Subsequent binding of RANKL to RANK finally results in osteoclast-mediated bone resorption (Simonet et al. 1997). Thus, it seems likely that differential WISP1 expression may also influence osteoclastogenesis by regulating the availability of TRAIL.

15.1.2. Intrinsic mediated apoptosis via p53

Several stimuli including oxidative stress, UV or gamma irradiation as well as kinase inhibitors and different cytotoxic compounds have been shown to activate the alternative mitochondrial (intrinsic) pathway of apoptosis. It is controlled by members of the BCL2 family that regulate cytochrome c release from the inter-membranous space of the mitochondria into the cytosol (Cory, Adams, et al. 2002). Following this major pathway, further important apoptotic factors were as well significantly differentially expressed between WISP1 down-regulated hMSCs and their control samples. Mostly, regulated genes concerning the second major pathway can be connected to p53-initiated apoptosis.

The tumour protein p53 is known as an essential transcription factor, regulating cell growth by repressing aberrant cell proliferation in response to multiple stimuli, like DNA damage and oncogene activation (Giaccia and Kastan 1998). Activation of p53 enhances DNA binding, thus triggering its transcriptional activity subsequent leading to cell cycle arrest and apoptosis induction. Initiation of an increased transcription of apoptosis responsive genes, often occur via p53 specific co-factors. One of those essential co-factors, the junction mediating and regulatory protein (JMY), is highly up-regulated in all examined WISP1 down-regulated samples. This protein acts by its complex formation with p300 in the nucleus, therefore enhancing the transcription activity of p53 apoptosis relevant target genes (Shikama et al. 1999).

Microarray data exhibited a differential expression of several p53 target genes. They can be divided in three subgroups, depending on their location within the cell membrane, cytoplasm or nucleus (Benchimol 2001). During the absence of WISP1 an increased expression of members of all three subgroups could be identified. First, the expression of apoptosis responsive membrane proteins, like the TRAIL binding death receptor DR5. Wu et al. (1997) discovered firstly an increased expression of this pro-apoptotic receptor, enabled through p53 after DNA damage (Wu et al. 1997). But also the transcription of the previously described protein BID, which is located in the cytoplasm, is clearly regulated through p53 (Sax et al. 2002). The third group comprises p53 target genes that encode proteins localized to the mitochondria. PMA-induced protein 1 (better known as NOXA), is an extensive characterized mediator of p53-dependent apoptosis (Oda et al. 2000) and was similarly up-regulated shortly after the down-regulation of WISP1 took place.

BID and NOXA are not only connected through their induced expression via p53, rather they are both pro-apoptotic BH3-only members of the BCL2 family. This family has been divided, based on structural similarities and functional criteria, in members with anti-apoptotic activity, e.g. B-cell lymphoma 2 (BCL2), BCL2 like 1 (BCLX) and members that promote cell death, e.g. NOXA, p53 up-regulated modulator of apoptosis (PUMA), bcl-2 interacting mediator of cell death (BIM), BCL2-associated X (BAX), BCL2-associated agonist of cell death (BAD) and BID (Gross et al. 1999; Puthalakath et al. 1999; Thomadaki and Scorilas 2006; Wolter et al. 1997). Activation of these proteins is affected by proteolysis, dephosphorylation and several other mechanisms (Adams 1998; Antonsson and Martinou 2000). After their activation, the pro-apoptotic proteins permeabilize the outer mitochondrial membrane and trigger the release of pro-apoptotic proteins, including cytochrome c (Kroemer and Reed 2000). Interestingly, cells with more pro-apoptotic BCL2 proteins are sensitive to death, whereas cells with an excess of protective family members are usually resistant. Yet, it is not well understood how cytochrome c release takes place, but Seo et al. (2003) assumed different mechanisms caused by either NOXA or BID. Mitochondrial breakdown and cytochrome c release through BID cleavage into tBID is mediated by BCL2-antagonist/killer 1 (BAK) or BAX oligomerization (Wang 2001; Wei et al. 2000, 2001), whereas NOXA-induced cytochrome c release is not dependent upon BAK oligomerization. Permeability transient related pore components seem to be responsible for NOXA-induced permeabilization of the mitochondrial outer membrane (Seo et al. 2003).

Interestingly, the previously described gene expression patterns, concerning p53-induced apoptosis in the absence of WISP1, are to a large part in accordance with findings of Su et al. (2002). They demonstrated the ability of WISP1 to prevent human lung carcinoma cells (H460) and human breast adenocarcinoma cells (MCF7) from undergoing apoptosis after DNA damage. Both cell types (containing wild type p53) were transfected with full-length Flag-tagged WISP1 and subsequent apoptosis induction via DNA damage clearly demonstrated an enhanced survival of WISP1 containing cells. Furthermore WISP1 thereby inhibits the mitochondrial release of cytochrome c and seems to circumvent cell death at a late stage in the p53-mediated apoptosis pathway. Another interesting and relevant study concerning p53 induced apoptosis and WISP1-signalling was published by Venkatesan et al. (2010). They characterized WISP1, similar to Su et al. (2002) as a survival factor, which has the ability to influence diverse survival pathways within a cell. The studies of Venkatesan et al. (2010) are based on the knowledge that WISP1 is over-expressed in several cancer cell lines and human tumours (Chen and Lau 2009; Yeger and Perbal 2007). Additionally, it is known that a forced expression of WISP1 initiates transformation and tumour formation of normal rat kidney fibroblast cells and nude mice (Pennica et al. 1998). Based on these facts, WISP1 seems to play a central role in tumour development. The research group of Venkatesan et al. (2010) used anthracycline antibiotic doxorubicin (DOX), a potent cancer chemotherapeutic agent, to induce cell death in adult mouse cardiomyocytes. DOX activates extrinsic- as well as intrinsic-mediated apoptotic signalling, which ultimately leads to cell death (Carvalho et al. 2009; Kotamraju et al. 2000; Olson and Mushlin 1990). Preincubation of mouse cardiomyocytes with full-length rWISP1 significantly attenuated DOX-mediated cell death (Venkatesan et al. 2010). DOX is also known to activate p53-dependent signalling pathways through DNA damage (Chua et al. 2006; L'Ecuyer et al. 2006). Venkatesan et al. (2010) clearly demonstrated that WISP1 suppressed DOX- mediated p53 activation. Similarly, WISP1 inhibited translocation of BAX to the mitochondria and circumvented DOX-induced cytochrome c release.

15.2. Initial apoptosis effects in WISP1 down-regulated Tc28a2 chondrocytes

15.2.1. WISP1 gene-silencing leads to differential gene expression patterns connected to the MAPK-signalling pathway

Additional microarray experiments were performed to investigate the effect of WISP1 gene-silencing on cell survival in the chondrocyte cell line Tc28a2. Similar to the procedure in hMSCs, microarray comparisons were designed to exhibit initial effects of apoptotic signalling shortly after WISP1 down-regulation took place. Surprisingly, the array data revealed remarkably differences compared to the findings concerning cell survival and apoptosis during WISP1 down-regulation in hMSCs. In Tc28a2 chondrocytes mainly genes connected to the mitogen-activated protein kinases (MAPK)-signalling pathway show differential expression patterns. These MAPKs are a group of serine/threonine kinases that are activated in response to a variety of extracellular stimuli. Activation results in three major types of MAP-kinase-cascades, usually named according to the main MAPK component of the cascades. The first cascade comprises signalling via extracellular signal regulated kinase 1 and -2 (ERK1/2), and is inducible by extracellular growth factor signals. The second one is mainly controlled by the stress-activated protein kinases p38-MAPK (α, β, γ and δ), inducible by cytokines and cellular stress. The third major MAPK cascade is mainly regulated through c-Jun amino-terminal kinases 1-3 (JNK1-3)-signalling, which is activated through hormones or cytokines, likewise to members of the TNF family.

Transmission of the signal via each cascade is mediated by sequential phosphorylation and activation of the components through various extracellular stimuli. MAPK-signalling thereby controls a large number of distinct and even opposing cellular processes such as proliferation, differentiation, survival, development, stress response, and apoptosis. Concerning apoptosis and cell survival, signalling through the JNK and p38 MAP-kinase cascades are, in general, associated with induction of cell death, whereas signalling through the ERK MAP-kinase cascade promotes cell growth and survival (Davis 2000; Yang et al. 1997). The impact of CCN family members on MAPK-signalling was first demonstrated by the activation of p38-MAPK and/or ERK cascades after stimulation with CYR61 and CTGF (Chen et al. 2001; Yosimichi et al. 2001). Furthermore, Kawaki et al. (2011) described an increased phosphorylation of ERK1/2 directly after osteoblast treatment with different recombinant CCN proteins. Thereby, WISP1 (as well as WISP2, CYR61 and CTGF) significantly activated ERK1/2. During this study, array analysis of the WISP1 down-regulated Tc28a2 chondrocytes identified several factors that finally point towards p38 and JNK phosphorylation as well as ERK1/2 inhibition. MAP2K7 for example, also known as JNK activating kinase 2 or MKK7, specifically activates JNK1 and -2 (Tournier et al. 2001). Deng et al. (2003) suggested that JNK activation via MAP2K7 is required for TNFα-induced CASP8 activation and apoptosis. There was no evidence for TNFα-induced apoptosis concerning the array data of WISP1 down-regulated chondrocytes, but some gene regulations seem to indicate an inhibition of NFκB (e.g. MAP3K3 and MAP3k7). NFκB activation also occurs via TNFα and the TNF-receptor and Javelaud and Besançon (2001) depict first a correlation between the NFκB and JNK pathways. Following the JNK or p38 pathway, both kinases translocate to the nucleus to activate transcription factors through phosphorylation (Davis 2000). Microarray data didn't confirm an increased gene expression of down-stream partners like ATF2, ELK1 or MEF2C, but it might be important to mention, that every array analysis reflects only one particular time point within a cell.

CHAPTER

SIXTEEN

EFFECT OF RECOMBINANT WISP PROTEINS ON TC28A2 CHONDOCYTES

WISP1 depleted Tc28a2 chondrocytes were partially treated with our previously produced (r)proteins of WISP1-T1 and WISP1-T2. Surprisingly, a highly significant self-regulation for both rWISP1 transcript variants was detectable after 24h. Furthermore it could be demonstrated that both transcript variants significantly increased their own expression, without affecting the down-regulation of the other one. This is a strong evidence for the effectiveness of both recombinant produced WISP1 protein variants in human cells. Additionally, Tc28a2 chondrocytes were treated with rWISP2. This cell line reflected no native WISP2 expression, thus it was unnecessary to reduce the endogenous protein amount prior to the treatment with rWISP2. Similar to the findings concerning WISP1 treatment, chondrocytes initiated their own WISP2 expression 24h after treatment. Thus, it is likewise a demonstration for the effectiveness of rWISP2 and moreover a novel finding in the research field comprising this CCN protein. To my knowledge, no other working group demonstrated an enforced endogenous WISP2 expression of cells that lack a native expression. How does en enforced endogenous WISP2 expression influence the chondrocyte cell line? Microarray analysis (n=3) were performed to investigate this question (data not shown). Unfortunately, no differentially gene expression patterns could be observed. Thus it is important to discuss, whether an enforced WISP2 expression has no effect on chondrocytes or maybe a change in experimental settings will help to exhibit gene regulations based on WISP2 expression. Isolation of WISP2 treated and native chondrocytes took place after cells reached nearly 100% confluence. Similarly, the native expression of different cells of the musculoskeletal system was validated. It is known that CCN proteins often are involved in proliferating processes. Therefore, further experiments are planned to examine WISP2 expression at different stages of confluence and during cell proliferation combined with several treatment experiments. Until then it cannot surely excluded that a native WISP2 expression exists, or an enforced expression constitutes to cellular differences compared to native cells.

16.1. rWISP1-T1 and -T2 don't prevent Tc28a2 chondrocytes for undergoing apoptosis after WISP1 gene-silencing

It was not possible to observe direct effects on cell survival after (r)protein treatment of the WISP1 down-regulated chondrocytes via microscopy. Why was it not possible to revert the process of cell death towards an enhanced vitality of the cells? Since our (r)proteins are able to induce their own endogenous expression, it can be excluded that the Fc-tag may disrupt

regulatory processes. Rather it is difficult to find the convenient time point to circumvent or reduce cell death induction. Protein treatment was performed a few hours subsequent to the transduction procedure, but an enhanced endogenous protein production was generally verified after additional 24h. Thus, it is possible that the time slot between treatment and resumption of endogenous protein production is too large to revert already induced cell death. Once apoptotic signalling has started, it may be difficult to obstruct the cascades before a point of no return is achieved. Additional, global gene expression patterns were examined using isolated mRNA of the previously described WISP1-T1 and -T2 treated cells (data not shown). Microarray analysis revealed no appreciable differences between shRNA5 transduced chondrocytes and such additional treated with rWISP1-T1 and -T2. Though, all shRNA5 transduced assays reflect similar regulations compared to their corresponding scrambled control samples - regardless if comparisons were performed with shRNA5 transduced samples or shRNA5 + rWISP1-T1 or -T2 treated samples (data not shown). This may supports the suggestion that self-regulation processes were initiated too late by protein treatments subsequent to the transduction procedure. It is also important to mention, that a time depend (r)protein treatment was performed without replicates and with only one concentration. Furthermore a certain assay to quantify apoptotic and viable cells was not available. Therefore, experiments should be repeated with improved experimental settings.

CHAPTER

SEVENTEEN

WISP1 AND ITS CONNECTION TO HUMAN HEALTH

Human WISP1 acts as a downstream factor of the canonical WNT-signalling pathway and its expression is regulated by β-catenin (Königshoff et al. 2009; Pennica et al. 1998; Xu et al. 2000). The canonical WNT-signalling pathway is known for the regulation of important cellular processes and aberrant expression of connected proteins is often described in combination with several medical conditions. However, WISP1 expression has been found in several cell types and prevalently an abnormal and increased WISP1 expression seems often to be responsible for different tumour types spreading over the whole human body. In vivo experiments exhibited an increased amount of full-length WISP1 mRNA and protein in colon adenocarcinomas, breast cancer, lung carcinoma and hepatocellular carcinoma (Calvisi et al. 2005; Margalit et al. 2003; Pennica et al. 1998; Xie et al. 2001). On the one hand, these findings clearly support the presumption for WISP1 as a survival factor for several cell types, because dysregulation of those proteins facilitate the formation of degenerated cell pools. On the other hand it might be an assertion for the distinct cluster of genes (23 interferon-inducible genes) connected to immuno-regulatory processes in the absence of WISP1.

Surprisingly, expression of all genes corresponding to this cluster is highly increased subsequent to the WISP1 down-regulation. It is known that hMSCs, derived from the bone marrow, constitutively secrete several cytokines important for haematopoiesis and immuno-modulatory processes (in 't Anker et al. 2003; Krampera et al. 2003). However, this study affords for the first time the influence of WISP1 on the activation of immuno-regulation through hMSCs. Microarray data suggests the importance for IFN1b signalling during this process. Interferon (IFN) inducing receptors, like the membrane bound toll like receptor 3 (TLR3) and receptors localized in the cytoplasm e.g. DDX58 and IFIH1, show an remarkable increase in regulation as well as the interferon IFNβ1 itself. In general, IFNs have been characterized as anti-proliferative cytokines, which act inter alia via the induction of cell cycle arrest in G1/G0 phase. IFNβ1 is such a member of the type I IFN family and has the ability to suppress tumour cell growth by induction of S-phase accumulation and apoptosis (Dong et al. 1999; Lokshin et al. 1995; Qin et al. 1997). These regulations support the previously described findings, which identified WISP1 as an important survival factor in hMSCs as well as its influence of immuno-regulatory processes mediated through primary cells.

17.1. WISP1 and its importance for the musculoskeletal system

The human musculoskeletal system persists of bones, cartilage, muscles, ligaments and associated connective tissues. A wide range of cell types, like multipotent stem cells (mesenchymals and haematopoetics), osteoblasts, chondrocytes, myoblasts and fibroblasts, are needed to es-

tablish and sustain this essential part of the human body. WNT-signalling is one of the most involved pathways to favour directly the regulation of skeletal development and tissue remodelling by modulating chondrocyte and osteoblast differentiation as well as joint formation (Hartmann and Tabin 2000, 2001; Rudnicki and Brown 1997). Given that WISP1 act as a downstream factor during WNT-signalling, assumption accrued this protein could play an important regulatory role in vertebrate skeletal development. A prominent role for WISP1 could be already confirmed for the signalling in primary hMSCs. French et al. (2004) illustrates the importance for full length WISP1 as an osteogenic potentiating factor, promoting MSC proliferation, osteoblast differentiation as well as repressing chondrocytic differentiation. This outcome is supported by Inkson et al. (2008) who further demonstrated the necessity of an additional trigger, like TGFβ or BMPs, to induce hMSC differentiation into osteoblasts. They further suggested the interaction of WISP1 with the proteoglycan biglycan (BGN) to control each other's activity in the regulation during osteoblast differentiation and proliferation (Inkson et al. 2009). Microarray data of WISP1 down-regulated hMSCs couldn't confirm an effect on the expression of TGFβ, BMPs or BGN. Instead of that, a second important binding partner of WISP1, the proteoglycan decorin (DCN) exhibits a strongly decreased expression during the absence of WISP1. The structure of DCN is closely related to that of biglycan and both proteins are highly expressed in bone tissues, but with observed differences in their distribution, indicating different roles during bone mineralization (Bianco et al. 1990; Ingram et al. 1993). In addition, the expression of the splicing variant WISP1-T2, lacking the VWC domain, could be observed in hMSCs (Inkson et al. 2008), osteoblasts and chondrocytes. (Yanagita et al. 2007) also confirmed an increased amount of WISP1-T2 during terminal chondrocyte differentiation. Compared to findings of French et al. (2004), who described a repressed chondrocytic differentiation mediated by full-length WISP1, differences in the effectiveness of both proteins could be assumed.

17.1.1. Influence of WISP1 on cartilage homeostasis

Adult cartilage is an avascular tissue composed mainly of chondrocytes, collagens and proteoglycans (Buckwalter and Mankin 1998; Palfrey and Davies 1966). Thereby, one major function of chondrocytes is the production and maintenance of the cartilaginous ECM by replacement of distinct matrix proteins. Influences on chondrocyte function are considered to be important in different human diseases, like the pathogenesis of osteoarthritis (OA) or rheumatoid arthritis (RA). A disruption of cartilage homeostasis may implicate the loss of collagens and proteoglycans from the ECM, which consequently impede the deposition of newly synthesized molecules. Thus, the pathogenesis of OA could be constrained by abnormal WNT-signalling that influences cartilage homeostasis (Loughlin et al. 2004). In this context, Blom et al. (2009) characterized expression patterns of WNT-inducible genes during experimental OA in mice and human OA. Interestingly, WISP1 expression was strongly increased in the synovium and cartilage of both examined OA types. Subsequent functional studies with rWISP1 in macrophages and chondrocytes led to the induction of different matrix metalloproteinases (MMPs) and aggrecanases (ADAMTSs) (Blom et al. 2009). Both are known to be mediating breakdown of extracellular cartilage matrix (Smith 1999).

Microarray analysis of WISP1 down-regulated Tc28a2 chondrocytes compared to their control samples revealed a remarkable cluster of distinct gene regulations that may affect cartilage homeostasis. Several expression patterns are in accordance with observations of Blom et al. (2009), e.g. the decrease of different extracellular proteases, like MMPS (MMP2, MMP11 and MMP16) and ADAMTSs (ADAMTS3, ADAMTS12 and ADAMTS17). MMP16 and ADAMTS17, a TNFα-converting enzyme, are both highly expressed in cartilage, but their specific roles in cartilage damage are still unclear (Leppert et al. 2001; Murphy and Lee 2005).

Further gene expression patterns, detectable during the absence of WISP1 in chondrocytes, seem to be important for cartilage homeostasis. Interestingly, all detected mRNA levels in this context are decreased in WISP1 down-regulated Tc28a2 chondrocytes compared to the corresponding control samples. The expression level of the cartilage linking protein HAPLN1, one major component of the cartilage extracellular matrix, was one of strongest effected transcripts in the absence of WISP1. Loss of HAPLN1 protein is associated with reduced aggrecan deposition and decreased numbers of hypertrophic chondrocytes in mice (Watanabe and Yamada 1999). It may also function as an inductor of the aggrecan and collagen type II synthesis in cartilage (McKenna et al. 1998). Therefore, dysregulated HAPLN1 expression seems crucial to proteoglycan aggregate formation and hypertrophic chondrocyte organization. Another protein, important in maintaining the chondrocyte phenotype is the transcription factor RUNX2. RUNX2 is a positive regulator of the transition from proliferating to hypertrophic chondrocytes, thus known as a hypertrophic marker. Interestingly, this protein is also strongly increased during the pathogenesis of OA (Martinez-Sanchez et al. 2012). At least we were able to detect significant over-representations of pathways important for cartilage homeostasis, like the MAPK-signalling pathway and focal adhesion. Both play essential roles in important biological processes including cell motility, cell proliferation, cell differentiation and regulation of gene expression. Focal adhesion, for example, controls cell-matrix adhesion via several ECM contact points, like trans-membrane receptors of the integrin family. Thereby, signalling cascades induce re-organization of the actin cytoskeleton, which constitutes the basis for changes in cell shape, motility, and gene expression. Focal adhesion is the most significant affected pathway detected through the KEGG pathway over-representation in WISP1 down-regulated chondrocytes. In contrast, MAPK-signalling is primary assumed to initiate apoptosis in chondrocytes as a result of the enforced down-regulation of WISP1 (Subsec. 15.2.1). Otherwise, it plays also an important role in cartilage homeostasis by affecting transcription levels of specific MMPs and cartilage-selective ECM associated proteins (Rockel et al. 2009; Séguin and Bernier 2003). Considering the fact that microarray analysis was actually performed to detect initial apoptotic effects in WISP1 down-regulated chondrocytes, findings concerning a disrupted cartilage homeostasis maybe closely linked to apoptosis in this chondrocyte cell line.

CHAPTER
EIGHTEEN

CONCLUSIONS

Recent studies have shown that WISP1 expression could mainly associate with development and disease by affecting cell survival, proliferation and cell differentiation. Results of this thesis emphasize the importance of regulatory mechanisms that influence cell survival of primary hMSCs and chondrocytes in the enforced absence of WISP1. For the first time, the dramatically effect of cell death, shortly after down-regulation of WISP1 could be confirmed in human musculoskeletal cells. In this context we were able to give new insights into gene expression changes, which indicate signalling of different apoptotic pathways, e.g. receptor- or p53-mediated apoptosis as well as MAPK-signalling. Since TRAIL and IFNβ, both remarkably increased in WISP1 down-regulated hMSCs, act as potent inhibitors for malignant cell growth *in vitro* knowledge about the connection with WISP1-signalling could help to find new therapeutic approaches concerning cancerogenesis and tumour growth. Moreover, the importance for WISP1-signalling in cartilage homeostasis seems to be manifested, since microarray data of WISP1 deficient chondrocytes revealed a distinct cluster of regulated genes important for ECM maintenance and hypertrophic chondrocyte organization. Several follow-up experiments are needed to investigate the role of WISP1-signalling in cartilage homeostasis and cell death, but this thesis generated an essential fundament for further examinations.

CHAPTER
NINETEEN

PERSPECTIVES

A difficult separation: Are the extrinsic- or intrinsic cascades responsible for apoptosis in WISP1 deficient hMSCs... or even both?

The affymetrix gene expression profile revealed different genes associated with both, the extrinsic- and intrinsic-mediated apoptosis pathways, after WISP1 down-regulation took place in MSCs. This is not exceptional, because different linker proteins like BID and p53, which directly connect the extrinsic and intrinsic mediated apoptosis, complicate a clearly separated examinations of both pathways. Nevertheless, it is important to molecularly dissect both major pathways for a better understanding of WISP1-signalling. Thus, different sets of experiments are planned to further investigate the role of extrinsic- and intrinsic-mediated apoptosis signals. One aim is the successful application of caspase inhibitors. They bind to the active site of a specific protease, e.g. CASP8 (extrinsic) or CASP9 (intrinsic), thereby inhibiting apoptosis in the absence of WISP1. Thus, the effective application of caspase inhibitors should enhance the cell viability during the WISP1 down-regulation. Additional, it is possible to stain CASP8 and CASP9 with specific fluorescence labelled caspase inhibitors (e.g. apoptosis detection assay FLICA) to distinguish between both initiator caspases. Due to the fact that both caspases are connected to one of both major apoptotic pathways, this staining procedure will give new insights in whether extrinsic or intrinsic stimuli are mainly responsible for hMSCS undergoing apoptosis in the absence of WISP1. We already established the general sulforhodamine-labelled VAD-FMK poly caspase inhibitor, detecting CASP1, -3, -4, -5, -6, -7, -8 and -9.

Furthermore, proteins that are involved in different apoptosis cascades can be visualized by immuno-cytochemistry labelling methods to infer their location within a cell. Cytochrome c, for example, promotes cell survival or death depending upon its intracellular location. In healthy cells it is a peripheral membrane protein of the mitochondria. When internal pro-apoptotic stimuli induce breakdown of the mitochondria, cytochrome c is released into the cytosol. There it leads to activation of caspases and thus triggers apoptosis. Another very interesting protein in this investigation could be the pro-apoptotic linker protein BID, which directly connects the mitochondrial pathway of apoptosis to the extrinsic pathway (Newsom-Davis et al. 2009). To investigate the protein localization, it is necessary to counterstain concurrently mitochondria and nuclei of the different cell types. Within this thesis, it was possible to establish the successful application of MitoTracker®Red to stain selective mitochondria in addition to the common nuclei marker DAPI. MitoTracker®Red is concentrated by active mitochondria and well retained during cell fixation.

Binding of TRAIL to its cell surface receptors results similarly in the activation of different caspases, which in turn inevitably initiate apoptosis. TRAIL has the ability to bind also to several decoy receptors that lack the death effector domain and thus are unable to promote

apoptosis-inducing signalling. OPG, for example, is one of the known decoy receptors, which protect cells against the apoptotic effects of TRAIL (Emery et al. 1998; Sheridan et al. 1997). A few years after OPG was identified as a modulator of osteoclastogenesis (Tsuda et al. 1997), it becomes more important as a survival factor for human breast and prostate cancer cells *in vivo* through inhibition of TRAIL induced apoptosis (Holen et al. 2002, 2005). Rachner et al. (2009) showed that differences in OPG expression affect the ability of breast cancer cell lines to evade TRAIL induced apoptosis. IL1β is one of the cytokines that has been shown to induce the OPG expression in breast cancer cells (Kapoor et al. 2008). Therefore, the apoptotic effect of IL1β-treated MSCs and chondrocytes, during WISP1 down-regulation, will be analysed in relation to the amount of endogenous expressed OPG. Additionally, gene-silencing of WISP1 with supplementary treatment of recombinant OPG are planned to discover survival effects between the shift in the TRAIL/OPG ratio. Depending on the knowledge that an increased amount of TRAIL enforces osteoclast differentiation, WISP1-signalling should also examined in detail concerning its role during the osteoclastogenesis.

In accordance to the literature, microarray data also support the importance of WISP1 for p53-dependent apoptotic signalling, thereby increasing the interest for further investigations of WISP1-signalling in future projects. It is well known that DNA damage initiates the stabilization of the p53 protein. This occurs, via phosphorylation or acetylation at several N-terminal residues, including Ser15, -20, -33 and -37 (Sakaguchi et al. 1998; Shieh et al. 1997, 1999; Siliciano et al. 1997). This knowledge is important for the use of specific antibodies against different activation sites and to examine the impact of p53 induction during the absence of WISP1 in hMSCs. After activation, p53 can either stimulate the death receptor pathway or the mitochondrial-mediated apoptosis signals. To further investigate the impact of p53 signalling during the absence of WISP1 in hMSCs, it is important to visualise its localization in WISP1 down-regulated cells in comparison to control cells. We already established the successful application of p53 specific, fluorescence labelled antibodies in hMSCs. The next step will include multiple staining experiments with double counterstain of mitochondria (MitoTracker®Red) and nuclei (DAPI), as soon as the p53 labelling is successful in MSCs during the WISP1 down-regulation. The findings concerning the impact of WISP1 on MAPK-signalling will be extended to the protein level by analysing possible alterations in phosphorylation levels of kinases and/or protein levels of regulating factors by western blotting. We will analyse phosphorylation of these kinases in addition to time- and concentration dependent application of (r)proteins. Kawaki et al. (2011) also demonstrated a successful annihilation of ERK1/2 activation through the application of specific MAPK inhibitors prior to the treatment with rCCN proteins. We plan to investigate the effect of three different MAPK inhibitors (MEK inhibitor PD98059, p38-MAPK inhibitor SB 203580 and JNK inhibitor 1; Merck) during the WISP1 down-regulation in Tc28a2 cells. The inhibitors will be used in independent and combined experiments with working concentration based on literature revue (Badger et al. 1998; Bain et al. 2003; Hung et al. 2008). Separated inhibition of the three major MAPK cascades will give new insights in the effectiveness of WISP1 on cell survival in chondrocytes.

It was not possible to revert the process of cell death in Tc28a2 chondrocytes through protein treatments with rWISP1-T1 or/and -T2. Improved experimental settings will therefore include different concentration steps of the (r)proteins that range from 100ng-1000ng. Treatments will be performed prior to and during the transduction to ensure a constant effectiveness of rWISP1-T1 and -T2. RNA isolation will be performed regularly to examine states of endogenous protein existence combined with subsequent apoptosis assays, like the previously described FLICA assay for a better validation of cell viability.

LIST OF TABLES

APPENDIX

A

DIFFERENTIALLY EXPRESSED PROBE SETS DURING MICROARRAY ANALYSIS OF WISP1 DOWN-REGULATED HMSCS

Table A.1.: *Listed are all 522 differentially expressed probe sets between shRNA5 transduced hMSC samples and their corresponding scrambled control assays (n=3). Probe sets are ordered according to their descending statistical score (logFc) from highest up-regulation to highest down-regulation. Additional information reflects the probe set ID, their corresponding gene symbol and name as well as the adjusted (corrected for multiple comparisons) p-value.*

Probe set ID	Gene symbol	Gene name	logFc	adj.p-val
242625_at	RSAD2	radical S-adenosyl methionine domain containing 2	4,49	$2{,}07 \times 10^{-5}$
213797_at	RSAD2	radical S-adenosyl methionine domain containing 2	4,41	$7{,}03 \times 10^{-6}$
226702_at	CMPK2	cytidine monophosphate (UMP-CMP) kinase 2, mitochondrial	4,38	$9{,}80 \times 10^{-6}$
226757_at	IFIT2	interferon-induced protein with tetratricopeptide repeats 2	4,05	$1{,}15 \times 10^{-6}$
210797_s_at	OASL	2'-5'-oligoadenylate synthetase-like	3,88	$9{,}61 \times 10^{-6}$
202687_s_at	TNFSF10	tumor necrosis factor (ligand) superfamily, member 10	3,77	$3{,}24 \times 10^{-5}$
205660_at	OASL	2'-5'-oligoadenylate synthetase-like	3,76	$8{,}08 \times 10^{-6}$
214329_x_at	TNFSF10	tumor necrosis factor (ligand) superfamily, member 10	3,69	$8{,}12 \times 10^{-6}$
223502_s_at	TNFSF13B	tumor necrosis factor (ligand) superfamily, member 13b	3,69	$6{,}59 \times 10^{-6}$
202688_at	TNFSF10	tumor necrosis factor (ligand) superfamily, member 10	3,64	$2{,}91 \times 10^{-5}$
217502_at	IFIT2	interferon-induced protein with tetratricopeptide repeats 2	3,56	$8{,}49 \times 10^{-7}$
223501_at	TNFSF13B	tumor necrosis factor (ligand) superfamily, member 13b	3,42	$2{,}28 \times 10^{-5}$
205552_s_at	OAS1	2',5'-oligoadenylate synthetase 1, 40/46kDa	3,28	$8{,}12 \times 10^{-6}$
33304_at	ISG20	interferon stimulated exonuclease gene 20kDa	3,24	$3{,}82 \times 10^{-5}$
202869_at	OAS1	2',5'-oligoadenylate synthetase 1, 40/46kDa	3,14	$2{,}08 \times 10^{-6}$
216598_s_at	CCL2	chemokine (C-C motif) ligand 2	3,06	$3{,}96 \times 10^{-6}$
219684_at	RTP4	receptor (chemosensory) transporter protein 4	2,94	$2{,}77 \times 10^{-5}$
219863_at	HERC5	hect domain and RLD 5	2,93	$9{,}33 \times 10^{-6}$
204439_at	IFI44L	interferon-induced protein 44-like	2,89	$1{,}73 \times 10^{-5}$
218943_s_at	DDX58	DEAD (Asp-Glu-Ala-Asp) box polypeptide 58	2,87	$8{,}71 \times 10^{-7}$

GENE ONTOLOGY ANALYSIS OF ALL SIGNIFICANTLY REGULATED GENES IN WISP1 DOWN-REGULATED HMSCS

Table B.1.: *All 456 significantly regulated genes, detected during the WISP1 array data analysis in hMSCs, were continuative assigned to GO terms and KEGG-signalling pathways. Illustrated are: the corresponding subclass name, the expected count, actual count and overall number of genes (N) associated to the GO/KEGG-term. These values are related to and corrected by the total number of all and differentially expressed corresponding genes present on the chip. The corresponding odds-ratio of corrected values is provided by the fraction (N/actual count). Corresponding p-values are results of the hyper-geometric tests.*

APPENDIX

C

DIFFERENTIALLY EXPRESSED PROBE SETS DURING MICROARRAY ANALYSIS OF WISP1 DOWN-REGULATED CHONDROCYTES

Table C.1.: *Listed are all 1687 differentially expressed probe sets between shRNA2 transduced chondrocyte samples and their corresponding scrambled control assays (n=5). Probe sets are ordered according to their descending statistical score (logFc) from highest up-regulation to highest down-regulation. Additional information reflects the probe set ID, their corresponding gene symbol and name as well as the adjusted (corrected for multiple comparisons) p-value.*

Probe set ID	Gene symbol	Gene name	logFc	adj.p-val
235258_at	DCP2	DCP2 decapping enzyme homolog (S. cerevisiae)	1,76	$1{,}61 \times 10^{-9}$
232331_at	NA	NA	1,70	$1{,}96 \times 10^{-9}$
204435_at	NUPL1	nucleoporin like 1	1,51	$6{,}59 \times 10^{-9}$

Probe set ID	Gene symbol	Gene name	logFc	adj.p-val
201124_at	ITGB5	integrin, beta 5	-0,97	$3{,}02 \times 10^{-6}$
217949_s_at	VKORC1	vitamin K epoxide reductase complex, subunit 1	-0,97	$1{,}38 \times 10^{-8}$
235363_at	NA	NA	-0,97	$6{,}96 \times 10^{-7}$
230383_x_at	NA	NA	-0,97	$3{,}08 \times 10^{-7}$
227138_at	CRTAP	cartilage associated protein	-0,97	$5{,}73 \times 10^{-6}$
225363_at	PTEN	phosphatase and tensin homolog	-0,97	$4{,}04 \times 10^{-7}$
238431_at	NA	NA	-0,98	$3{,}43 \times 10^{-7}$
203881_s_at	DMD	dystrophin	-0,98	$4{,}40 \times 10^{-6}$
203044_at	CHSY1	chondroitin sulfate synthase 1	-0,98	$6{,}88 \times 10^{-8}$
201430_s_at	DPYSL3	dihydropyrimidinase-like 3	-0,98	$1{,}45 \times 10^{-5}$
1559007_s_at	NA	NA	-0,98	$4{,}57 \times 10^{-6}$
230154_at	NA	NA	-0,98	$1{,}19 \times 10^{-5}$
224778_s_at	NA	NA	-0,98	$3{,}97 \times 10^{-8}$
218057_x_at	COX4NB	COX4 neighbor	-0,98	$6{,}58 \times 10^{-9}$
201765_s_at	HEXA	hexosaminidase A (alpha polypeptide)	-0,98	$1{,}81 \times 10^{-7}$
208944_at	TGFBR2	transforming growth factor, beta receptor II (70/80kDa)	-0,98	$2{,}49 \times 10^{-8}$
227518_at	SLC35E1	solute carrier family 35, member E1	-0,98	$4{,}53 \times 10^{-7}$
228335_at	CLDN11	claudin 11	-0,99	$1{,}58 \times 10^{-7}$
211953_s_at	IPO5	importin 5	-0,99	$1{,}81 \times 10^{-7}$
218847_at	IGF2BP2	insulin-like growth factor 2 mRNA binding protein 2	-0,99	$6{,}35 \times 10^{-7}$
222559_s_at	RPRD1A	regulation of nuclear pre-mRNA domain containing 1A	-0,99	$2{,}48 \times 10^{-6}$
200931_s_at	VCL	vinculin	-0,99	$3{,}39 \times 10^{-9}$
228482_at	NA	NA	-0,99	$4{,}35 \times 10^{-6}$
235093_at	PEX13	peroxisomal biogenesis factor 13	-0,99	$6{,}98 \times 10^{-8}$
203852_s_at	NA	NA	-0,99	$4{,}04 \times 10^{-6}$
230302_at	NA	NA	-0,99	$4{,}37 \times 10^{-8}$
231233_at	NA	NA	-0,99	$4{,}46 \times 10^{-6}$
213388_at	PDE4DIP	phosphodiesterase 4D interacting protein	-0,99	$3{,}03 \times 10^{-6}$
215128_at	NA	NA	-1,00	$1{,}08 \times 10^{-6}$
225951_s_at	CHD2	chromodomain helicase DNA binding protein 2	-1,00	$1{,}73 \times 10^{-7}$
202498_s_at	SLC2A3	solute carrier family 2 (facilitated glucose transporter), member 3	-1,00	$4{,}84 \times 10^{-6}$
232231_at	RUNX2	runt-related transcription factor 2	-1,00	$8{,}86 \times 10^{-6}$
225865_x_at	TH1L	TH1-like (Drosophila)	-1,00	$4{,}28 \times 10^{-9}$
222558_at	RPRD1A	regulation of nuclear pre-mRNA domain containing 1A	-1,00	$1{,}97 \times 10^{-7}$
211954_s_at	IPO5	importin 5	-1,00	$1{,}48 \times 10^{-8}$
224769_at	NA	NA	-1,00	$1{,}64 \times 10^{-8}$
219283_at	C1GALT1C1	C1GALT1-specific chaperone 1	-1,00	$2{,}58 \times 10^{-7}$
227357_at	TAB3	TGF-beta activated kinase 1/MAP3K7 binding protein 3	-1,00	$1{,}51 \times 10^{-7}$
243999_at	SLFN5	schlafen family member 5	-1,00	$4{,}29 \times 10^{-7}$
232914_s_at	SYTL2	synaptotagmin-like 2	-1,01	$5{,}13 \times 10^{-7}$
224882_at	ACSS1	acyl-CoA synthetase short-chain family member 1	-1,01	$1{,}34 \times 10^{-8}$

Table C.1.: *(...continued)*

Probe set ID	Gene symbol	Gene name	logFc	adj.p-val
1553117_a_at	STK38	serine/threonine kinase 38	-1,01	$3{,}63 \times 10^{-6}$
217645_at	COX16	COX16 cytochrome c oxidase assembly homolog (S. cerevisiae)	-1,01	$3{,}73 \times 10^{-6}$
200845_s_at	PRDX6	peroxiredoxin 6	-1,01	$1{,}70 \times 10^{-7}$
227123_at	RAB3B	RAB3B, member RAS oncogene family	-1,01	$1{,}54 \times 10^{-5}$
207992_s_at	AMPD3	adenosine monophosphate deaminase 3	-1,02	$2{,}00 \times 10^{-7}$
225276_at	GSPT1	G1 to S phase transition 1	-1,02	$2{,}78 \times 10^{-8}$
225006_x_at	TH1L	TH1-like (Drosophila)	-1,02	$7{,}71 \times 10^{-9}$
222504_s_at	COX4NB	COX4 neighbor	-1,02	$3{,}96 \times 10^{-8}$
227363_s_at	COX4NB	COX4 neighbor	-1,02	$1{,}41 \times 10^{-8}$
218362_s_at	DIS3	DIS3 mitotic control homolog (S. cerevisiae)	-1,02	$1{,}61 \times 10^{-7}$
225261_x_at	TH1L	TH1-like (Drosophila)	-1,02	$5{,}10 \times 10^{-9}$
202213_s_at	CUL4B	cullin 4B	-1,02	$1{,}55 \times 10^{-5}$
226591_at	SNRPN	small nuclear ribonucleoprotein polypeptide N	-1,02	$1{,}48 \times 10^{-5}$
202118_s_at	CPNE3	copine III	-1,02	$5{,}59 \times 10^{-6}$
230183_at	EXT1	exostoses (multiple) 1	-1,02	$1{,}81 \times 10^{-7}$
202625_at	LYN	v-yes-1 Yamaguchi sarcoma viral related oncogene homolog	-1,03	$1{,}17 \times 10^{-8}$
208932_at	PPP4C	protein phosphatase 4 (formerly X), catalytic subunit	-1,03	$9{,}42 \times 10^{-9}$
242263_at	TMED5	transmembrane emp24 protein transport domain containing 5	-1,03	$3{,}40 \times 10^{-6}$
1569129_s_at	C3orf38	chromosome 3 open reading frame 38	-1,03	$1{,}00 \times 10^{-5}$
230238_at	ANKRD43	ankyrin repeat domain 43	-1,03	$7{,}74 \times 10^{-7}$
201150_s_at	TIMP3	TIMP metallopeptidase inhibitor 3	-1,03	$1{,}07 \times 10^{-6}$
203232_s_at	ATXN1	ataxin 1	-1,03	$6{,}97 \times 10^{-7}$
224940_s_at	PAPPA	pregnancy-associated plasma protein A, pappalysin 1	-1,03	$6{,}42 \times 10^{-7}$
202604_x_at	ADAM10	ADAM metallopeptidase domain 10	-1,03	$1{,}45 \times 10^{-7}$
235079_at	NA	NA	-1,03	$2{,}08 \times 10^{-6}$
200713_s_at	MAPRE1	microtubule-associated protein, RP/EB family, member 1	-1,03	$7{,}80 \times 10^{-9}$
225842_at	PHLDA1	pleckstrin homology-like domain, family A, member 1	-1,03	$1{,}10 \times 10^{-5}$
235635_at	ARHGAP5	Rho GTPase activating protein 5	-1,03	$1{,}53 \times 10^{-6}$
200623_s_at	CALM3	calmodulin 3 (phosphorylase kinase, delta)	-1,04	$1{,}93 \times 10^{-8}$
220607_x_at	TH1L	TH1-like (Drosophila)	-1,04	$6{,}59 \times 10^{-9}$
218170_at	ISOC1	isochorismatase domain containing 1	-1,04	$1{,}58 \times 10^{-7}$
218042_at	COPS4	COP9 constitutive photomorphogenic homolog subunit 4 (Arabidopsis)	-1,04	$5{,}68 \times 10^{-8}$
228569_at	PAPOLA	poly(A) polymerase alpha	-1,04	$3{,}93 \times 10^{-6}$
221906_at	TXNRD3	thioredoxin reductase 3	-1,04	$3{,}03 \times 10^{-7}$
226934_at	CPSF6	cleavage and polyadenylation specific factor 6, 68kDa	-1,04	$8{,}29 \times 10^{-7}$
214953_s_at	APP	amyloid beta (A4) precursor protein	-1,04	$4{,}89 \times 10^{-7}$
228555_at	CAMK2D	calcium/calmodulin-dependent protein kinase II delta	-1,04	$2{,}76 \times 10^{-7}$
231894_at	NA	NA	-1,04	$1{,}78 \times 10^{-8}$
225311_at	IVD	isovaleryl Coenzyme A dehydrogenase	-1,04	$1{,}13 \times 10^{-8}$

GENE ONTOLOGY ANALYSIS OF ALL SIGNIFICANTLY REGULATED GENES IN WISP1 DOWN-REGULATED CHONDROCYTES

Table D.1.: *All 1402 significantly regulated genes, detected during the WISP1 array data analysis in chondrocytes, were continuative assigned to GO terms and KEGG-signalling pathways. Illustrated are: the corresponding subclass name, the expected count, actual count and overall number of genes (N) associated to the GO/KEGG-term. These values are related to and corrected by the total number of all and differentially expressed corresponding genes present on the chip. The corresponding odds-ratio of corrected values is provided by the fraction (N/actual count). Corresponding p-values are results of the hyper-geometric tests.*

μM	micromolar=micromol per litre

LIST OF PUBLICATIONS

Journal publications

Schlegelmilch K., A. Keller, V. Zehe, S. Hondke, L. Klein-Hitpass, N. Schütze. (2012, submitted) "Identification of WISP1 as an important survival factor in human mesenchymal stem cells."

Nanda I., **K. Schlegelmilch**, T. Haaf, M. Schartl, M. Schmid (2008). "Synteny conservation of the Z chromosome in 14 avian species (11 families) supports a role for Z dosage in avian sex determination." In: Cytogenet Genome Res 122.2, pp. 150-6.

Oral presentations

Schlegelmilch K., A. Keller A., V. Zehe, R. Schenk, N. Schütze (24.-16.03.2011). "Humane mesenchymale Stammzellen (hMSCs) und Tc28a2 Chondrozyten benötigen WISP1 zum Überleben." Osteology Congress, Fürth, Germany.

Hilpert S., V. Monz, **K. Schlegelmilch**, A. Keller, S. Jatzke, N. Schütze (24.-16.03.2011) "Funktionsaufklärung von WISP3 Protein in humanen Chondrozyten." Osteology Congress 2011, Fürth, Germany.

Schlegelmilch K., A. Keller, V. Zehe, N. Schütze (20.-24.10.2010). "Molecular elucidation of WISP1 functions in hMSCs and chondrocytes." 6th International Workshop on the CC Family of Genes, Newcastle, Northern Ireland.

Poster presentations

Hondke S., S. Hilpert, V. Zehe, **K. Schlegelmilch**, A. Keller, N. Schütze (23.-25.05.2012). "WISP1 and -3 affect cell survival in human mesenchymal stem cells (hMSCs) and Tc28a2 chondrocytes". 3rd International Conference of Strategies in Tissue Engineering, Würzburg, Germany.

Hondke S., S. Hilpert, V. Zehe, **K. Schlegelmilch**, A. Keller, S. Wiesner, N. Schütze (29.-31.03.2012). "Funktionsaufklärung von WISP3 Protein in humanen Chondrozyten und humanen mesenchymalen Stammzellen." Osteology Congress, Basel, Switzerland.

Dotterweich J., J. Schneidereit, **K. Schlegelmilch**, L. Klein-Hitpass, F. Jakob, N. Schütze (23.-24.03.2012). "Molekulare Studien zur Interaktion von mesenchymalen Stammzellen mit Myelomzellen." Osteooncology Congress, Tübingen, Germany.

Laug R., V. Zehe, **K. Schlegelmilch**, S. Kunzmann, A. Keller, F. Jakob, N. Schütze (24.-26.03.2011) Funktion von CTGF in Lungenendothelzellen und mesenchymalen Stammzellen. Osteology Congress 2011, Fürth, Germany.

Schlegelmilch K., V. Monz, F. Jakob, N. Schütze (03.-06.03.2010). "Funktionsaufklärung von WISP-Proteinen in mesenchymalen Stammzellen (MSCs) und Chondrozyten." Osteology Congress, Berlin, Germany.

Schlegelmilch K., V. Monz, M. Kunz, J. Pfeilschifter, N. Schütze (11.-15.09.2009). "Towards elucidation of WISP protein function in mesenchymal stem cells and chondrocytes." ASBMR 31st Annual Meeting, Denver, Colorado, USA.

Schlegelmilch K., S. Hilpert, S. Jatzke, F. Jakob, N. Schütze (04.-07.03.2009). "Rekombinante Proteinherstellung und Expressionsanalysen von WISP-Proteinen." Osteology Congress, Frankfurt, Germany.

Schlegelmilch K., R. Schenk, S. Jatzke, U. Nöth, L. Klein-Hitpass, F. Jakob, N. Schütze (09.-11.10.2008). "Function of WISP proteins in human mesenchymal stem cells." BioStar 3rd Congress on Regenerative Biology and Medicine, Stuttgart, Germany.

ERKLÄRUNG

Hiermit erkläre ich ehrenwörtlich, dass ich die vorliegende Dissertation selbständig angefertigt und keine anderen als die angegebenen Quellen und Hilfsmittel verwendet habe. Die Dissertation wurde bisher weder in gleicher noch ähnlicher Form in einem anderen Prüfungsverfahren vorgelegt. Außer dem Diplom in Biologie von der Universität Würzburg habe ich bisher keine weiteren akademischen Grade erworben oder versucht zu erwerben.

Würzburg, den 26. 4. 2012

Katrin Schlegelmilch
