

Transdifferentiation of Human Mesenchymal Stem Cells

Dissertation zur Erlangung des naturwissenschaftlichen
Doktorgrades der Julius-Maximilians-Universität Würzburg

vorgelegt von

Tatjana Schilling

aus

San Miguel de Tucuman, Argentinien

Würzburg, 2007

Eingereicht am:.....

Mitglieder der Promotionskommission:

Vorsitzender:..... Prof. Dr. Martin J. Müller

Gutachter:..... PD Dr. Norbert Schütze

Gutachter:..... Prof. Dr. Georg Krohne

Tag des Promotionskolloquiums:.....

Doktorurkunde ausgehändigt am:.....

Hiermit erkläre ich ehrenwörtlich, dass ich die vorliegende Dissertation selbstständig angefertigt und keine anderen als die von mir angegebenen Hilfsmittel und Quellen verwendet habe. Des Weiteren erkläre ich, dass diese Arbeit weder in gleicher noch in ähnlicher Form in einem Prüfungsverfahren vorgelegen hat und ich noch keinen Promotionsversuch unternommen habe.

Gerbrunn, 4. Mai 2007

1 Summary

1.1 Summary

With ageing, the loss of bone mass correlates with the expansion of adipose tissue in human bone marrow thus facilitating bone-related diseases like osteopenia and osteoporosis. The molecular mechanisms underlying these events are still largely unknown. Reduced osteogenesis and concurrently enhanced adipogenesis might not only occur due to the impairment of conventional osteogenic differentiation originating from mesenchymal stem cells (MSCs). Additionally, transdifferentiation of (pre-)osteoblasts into adipocytes could contribute to the fatty conversion. Therefore, the aim of the present study was to prove the existence of transdifferentiation between the adipogenic and osteogenic lineage and to elucidate molecular mechanisms underlying this phenomenon.

At first, a cell culture system of primary human MSCs was established that allowed for differentiation into the adipogenic and osteogenic lineage and proved that the MSC-derived adipocytes and pre-osteoblasts were capable of transdifferentiation (reprogramming) from one into the other lineage. Thereby, lineage-specific markers were completely reversed after reprogramming of pre-osteoblasts into adipocytes. The osteogenic transdifferentiation of adipocytes was slightly less efficient since osteogenic markers were present but the adipogenic ones partly persisted. Hence, plasticity also reached into the differentiation pathways of both lineages and the better performance of adipogenic reprogramming further supported the assumption of its occurrence *in vivo*.

The subsequent examination of gene expression changes by microarray analyses that compared transdifferentiated cells with conventionally differentiated ones revealed high numbers of reproducibly regulated genes shortly after initiation of adipogenic and osteogenic reprogramming. Thereof, many genes were correlated with metabolism, transcription, and signal transduction as FGF, IGF, and Wnt signalling, but only few of the established adipogenesis- and none of the osteogenesis-associated marker genes were detected within 24 h after initiation of transdifferentiation.

To find possible key control factors of transdifferentiation amongst the huge amount of regulated genes, a novel bioinformatic scoring scheme was developed that ranked genes due to their potential relevance for reprogramming. Besides the reproducibility and level of their regulation, also the possible reciprocity between the adipogenic and osteogenic transdifferentiation pathway was taken into account. Fibroblast growth factor 1 (FGF1) that ranked as one of the leading candidates to govern reprogramming was proven to inhibit adipogenic differentiation as well as adipogenic transdifferentiation in our cell culture system.

Further examination of the FGF signalling pathway and other highly ranked genes could help to better understand the age-related fatty degeneration at the molecular level and therefore provide target molecules for therapeutic modulation of the plasticity of both lineages in order to inhibit adipogenic degeneration and to enhance osteogenesis.

1.2 Zusammenfassung

Der Verlust an Knochenmasse im Alter ist mit der Ausbreitung von Fettgewebe im menschlichen Knochenmark assoziiert und fördert daher auch knochenspezifische Erkrankungen wie Osteopenie und Osteoporose. Die diesen Ereignissen zu Grunde liegenden Mechanismen sind immer noch weitgehend unbekannt. Die abnehmende Osteogenese und die gleichzeitig zunehmende Adipogenese treten wahrscheinlich nicht nur wegen der Beeinträchtigung der konventionellen osteogenen Differenzierung von mesenchymalen Stammzellen (MSZ) auf. Zusätzlich könnte auch die Transdifferenzierung (Reprogrammierung) von Osteoblasten(vorläufern) zu Adipozyten zur fettigen Umwandlung beitragen. Das Ziel der vorliegenden Studie war es daher, die Existenz der Transdifferenzierung zwischen dem adipogenen und osteogenen Differenzierungsweg nachzuweisen und die molekularen Mechanismen aufzuklären, die diesem Phänomen zu Grunde liegen.

Zunächst wurde ein Zellkultursystem primärer mesenchymaler Stammzellen etabliert, in dem eine Differenzierung zu Adipozyten und Osteoblasten durchgeführt werden konnte, und nachgewiesen, dass aus MSZ erhaltene Adipozyten und Osteoblastenvorläufer von einer zur anderen Zelllinie transdifferenziert (reprogrammiert) werden können. Dabei wurden die zelllinienspezifischen Marker nach der Reprogrammierung von Osteoblastenvorläufern zu Adipozyten vollständig umgekehrt. Die osteogene Transdifferenzierung von Adipozyten war etwas weniger effizient, da die osteogenen Marker zwar vorhanden waren, aber auch die adipogenen Marker weiterhin auftraten. Die Plastizität erstreckte sich also auch auf die Differenzierungswege der beiden Zellpopulationen, wobei das bessere Ergebnis bezüglich der adipogenen Reprogrammierung die Annahme ihres Auftretens *in vivo* weiter unterstützte. Die nachfolgende Untersuchung von Genexpressionsänderungen mittels Mikroarray-Analysen, die transdifferenzierte mit konventionell differenzierten Zellen verglichen, führte kurz nach Initiation der adipogenen und osteogenen Transdifferenzierung zum Auffinden zahlreicher, reproduzierbar regulierter Gene. Viele dieser Gene standen mit Metabolismus, Transkription und Signaltransduktion wie dem FGF-, IGF- und Wnt-Signalweg in Zusammenhang, es wurden allerdings nur einige Adipogenese- und keinerlei Osteogenese-assoziierte Markergene innerhalb 24 h nach Initiation der Transdifferenzierung detektiert. Um unter der großen Zahl an regulierten Genen mögliche Schlüsselkontrollfaktoren der

Transdifferenzierung zu finden, wurde ein neuartiges, bioinformatisches Punktesystem entwickelt, das Gene entsprechend ihrer potenziellen Relevanz für die Reprogrammierung auflistete. Dabei wurde neben der Reproduzierbarkeit und dem Ausmaß ihrer Regulation auch eine mögliche Reziprozität der Regulation zwischen dem adipogenen und osteogenen Transdifferenzierungsweg berücksichtigt. Es konnte nachgewiesen werden, dass der Fibroblastenwachstumsfaktor 1 (FGF1), der als einer der Hauptkandidaten für die Steuerung der Reprogrammierung eingeordnet worden war, in unserem Zellkultursystem sowohl die adipogene Differenzierung als auch die adipogene Transdifferenzierung hemmt.

Die weitere Untersuchung des FGF-Signalwegs und anderer, hoch gelisteter Gene könnte zum besseren Verständnis der altersbezogenen fettigen Degeneration auf molekularer Ebene beitragen und daher Zielmoleküle liefern, die eine therapeutische Beeinflussung der Plastizität zwischen beiden Zelllinien zur Verhinderung der fettigen Degeneration und zur Förderung der Osteogenese erlauben.

2 Introduction

2.1 Osteoporosis and the fatty degeneration of the bone marrow

With ageing, degenerative processes of the musculoskeletal system give rise to several painful diseases like osteoarthritis, tendinosis, and osteoporosis. While osteoarthritis and tendinosis affect the joints, osteoporosis is characterised by the general loss of bone mass [Rössler and Rüter, 2000]. During ongoing osteoporosis, bone density declines at first in the spine, ribcage, pelvis, and hip, thus facilitating the risk of fractures in these skeletal areas [Adler, 1983a; Brügger, 1980]. Thereby, age-related lower calcium absorption in the stomach and intestine, tissue hypoxia as well as changes of the endocrine metabolism, especially estrogen deficiency in postmenopausal women, account for these changes. At the histological level, these alterations disrupt the setup of the osteoid that is comprised of osteoblasts and not yet mineralised extracellular matrix and participates in bone remodelling [Bartl, 2001; Henriksen et al., 2007].

During progressing osteoporosis, the bone volume declines in favour of spreading marrow volume [Adler, 1983a; Justesen et al., 2001]. Since adipose tissue simultaneously augments in the bone marrow, it has been assumed that an inverse relationship between decreasing osteogenesis and increasing adipogenesis exists [Beresford et al., 1992; Burkhardt et al., 1987; Gimble et al., 2006; Koo et al., 1998; Meunier et al., 1971; Pei and Tontonoz, 2004]. Thereby, osteoporosis has even been discussed as the obesity of bone [Rosen and Bouxsein, 2006]. Moreover, osteopenia was detected in a mouse model with accelerated adipogenesis which further supports the detrimental effect of the imbalance between osteogenesis and adipogenesis on bone mass [Klein et al., 2004].

2.2 Adipose and bone tissue

2.2.1 Adipose tissue

Adipose tissue is composed of adipocytes that produce connective tissue matrix also containing nerve tissue, stromavascular cells, and immune cells [Frayn et al., 2003].

Thereby, brown and white adipocytes both accumulate lipids but carry out opposing functions. Brown adipose tissue stores less lipids and is involved in thermogenesis as an energy-dissipating organ while white adipose tissue strongly accumulates lipids serving as main energy storage of the organism [Krug and Ehrhart-Bornstein, 2005; Trayhurn et al., 2006]. Additionally, white adipose tissue secretes hormones and signalling factors that affect various physiological and pathophysiological processes [Cousin et al., 1993; Wajchenberg, 2000]. The metabolism of adipose tissues and the release of adipocyte-secreted proteins (adipokines) influence energy homeostasis, insulin sensitivity, and vascular homeostasis of

the organism [de Meis et al., 2006; Guerre-Millo, 2004; Trayhurn et al., 2006]. Adipokines like leptin and adiponectin (also called ADIPOQ) mediate beneficial effects on insulin sensitivity, energy balance, and vasculature (fig. 1) [Farooqi et al., 2002; Maeda et al., 2001; Yu et al., 2002]. In contrast, high amounts of other adipokines provoke detrimental effects. Tumour necrosis factor α (TNF α), interleukin 6 (IL6), and resistin generate insulin resistance while the effects of angiotensinogen (AGE) and plasminogen activator inhibitor 1 (PAI-1, also called SERPINE1) have been correlated with vascular complications of obesity, e.g. hypertension and fibrinolysis [Ailhaud et al., 2000; Mavri et al., 2001]. Moreover, acetylation-stimulating protein (ASP) stimulates triglyceride storage in adipocytes by enhancement of glucose transport and inhibition of lipolysis [Cianflone et al., 1999].

Fig. 1 Influence of adipokines on energy homeostasis, insulin sensitivity, and vascular homeostasis

Adipokines secreted by adipocytes of white adipose tissue (in the middle) influence several physiological processes. Excessive amounts of ASP, TNF α , IL6, and resistin disrupt insulin action in muscle and liver, whereas the raise of AGE and PAI-1 promotes hypertension and impaired fibrinolysis correlated with obesity. Moreover, leptin maintains the energy homeostasis and enhances insulin sensitivity as well as adiponectin. Figure by Guerre-Millo [2004].

2.2.2 Bone tissue

Bone functions to support the body thereby determining its shape and protecting the soft tissues [Adler, 1983b]. The shape of the skeleton and hence the structure of its bones is

adapted to the physical load exposure by bone resorption and bone accrual (see 2.2.3). Moreover, bone enables movement together with the skeletal muscles, tendons, ligaments, and joints.

Besides support of the body, the metabolic function of bone plays a very important role. Since calcium ion levels control organ and cellular activities, the storage and release of calcium and phosphate ions from bone is required to balance the serum levels of these ions [Martin, 1983; Rössler and Rüter, 2000] (fig. 2). Calcium and phosphate absorption via nutrition is controlled by 1,25-dihydroxyvitamin D₃ thus making calcium and phosphate available for mineralisation of bone [Bronner, 1994; Misof et al., 2003]. Further hormones including parathyroid hormone (PTH), epidermal growth factor, prostaglandins, and osteoclast activating factor, stimulate the release of minerals and organic compounds from bone. In contrast, hormonal inhibitors of bone resorption like calcitonin (CT) and glucocorticoids block calcium release from bone tissue. Disturbance of this storage and release mechanisms not only affects calcium metabolism but also causes changes regarding the toughness of bone.

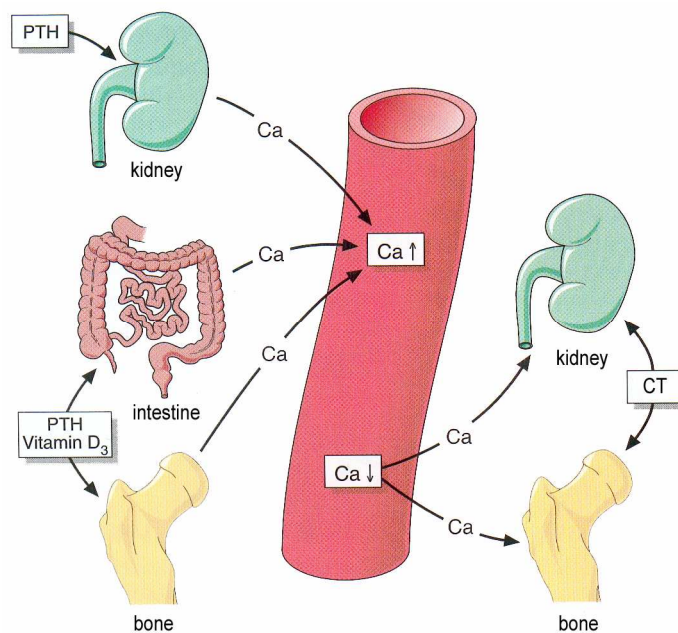

Fig. 2 Regulation of calcium metabolism

Parathyroid hormone (PTH) and 1,25-dihydroxyvitamin D₃ promote absorption of calcium (Ca) in the intestine and make Ca available from bone whereas PTH additionally represses calcium excretion via the kidney thus elevating Ca serum levels. Calcitonin (CT) increases calcium deposition in bone as well as Ca excretion in the kidney thereby diminishing Ca serum levels. Figure adapted from Rössler and Rüter [2000].

Bone tissue consists of 10% water, more than 70% inorganic, and approximately 20% organic matrix including bone cells like osteoblasts and osteocytes that are supplied with nutrients and oxygen by blood vessels [Adler, 1983b]. The osteoid comprises organic bone matrix and embedded osteoblasts that produce the matrix components before becoming

osteocytes. The organic matrix itself serves as a deposition site for minerals and is composed of 90% collagen type I and 10% other, non-collagenous proteins (e.g. glycoproteins like osteocalcin, osteonectin, integrin-binding sialoprotein, and osteopontin) and proteoglycans. The inorganic portion of bone matrix is composed of 90% calcium phosphate and 10% calcium carbonate. Thereby, calcium forms hydroxyapatite crystals incorporated into the organic matrix. The bone tissue encloses the bone marrow, which is located within the medullary cavity of long bones and the interstices of cancellous bone. Bone marrow contains hematopoietic as well as mesenchymal precursor cells whereas the former give rise to blood cells and the latter can generate several mesenchymal tissues (see 2.3.1).

2.2.3 Bone remodelling

Ossification of the skeleton is not completed until adolescence. Even afterwards bone is continuously remodelled in order to meet changing needs as well as to maintain bone quality and strength by replacement of aged bone matrix of lower density and reduced quality [Bartl, 2001; Caplan, 2005; Henriksen et al., 2007; Martin, 1983]. Bone remodelling thus comprises bone resorption as well as bone accrual and therefore provides calcium mobilisation and deposition within calcium homeostasis, replacement of old bone tissue, adaptation to altered loads, and repair of injured bone.

The circle of bone remodelling consists of distinct phases beginning with the activation of multinucleated osteoclasts (fig. 3). Osteoclasts are derived from monocytes of the hematopoietic lineage and function as bone resorbing cells [Bartl, 2001; Väänänen et al., 2000]. They attach to the bone surface with their ruffled border and secrete proteolytic enzymes that dissolve crystalline hydroxyapatite. The remaining organic matrix is absorbed by phagocytosis and is digested in the cytoplasm of the osteoclasts. Recruitment of osteoclasts to the site of bone resorption is controlled by several hormones (e.g. PTH, estrogen, and leptin) and growth factors. Subsequently, the reversal phase provides smoothing of the resorption lacuna and activation of osteoblasts. Osteoblasts derived from MSCs form the osteoid by synthesis of bone matrix that consists at first mainly of collagen type I (formation early phase) and serves as a scaffold for mineralisation lasting several weeks (formation late phase). About 10% of the osteoblasts are incorporated into the newly formed bone matrix and differentiate into osteocytes. These osteocytes reside in lacunae, which are connected by branched canaliculi and mediate metabolite transport inside the bone matrix. In the final quiescence phase, the surface of the bone is covered by lining cells, which are supposed to represent inactive osteoblasts and to protect bone. Additionally, lining cells as well as osteoblasts express membrane-bound and soluble molecules like receptor activator of NF- κ B ligand (RANKL) and osteoprotegerin (also called tumour necrosis factor receptor superfamily member 11b, TNFRSF11B) that influence osteoclast differentiation [Hsu

et al., 1999; Lacey et al., 1998]. Thereby, RANKL interacts with osteoclast-specific RANK thus able to stimulate osteoclast differentiation. Contrarily, TNFRSF11B acts as a decoy receptor for RANKL thereby neutralising its osteoclastogenesis-stimulating effect. Further compounds like cyclosporin A and interferon γ as well as calcium ions have been reported to strongly diminish the resorption of bone matrix [Fuller et al., 2007].

Additionally, Wnt signalling has been shown to regulate osteogenesis *in vitro* and *in vivo* (see 2.3.3). Recent data also suggest that Wnt signalling not only affects osteogenesis but also influences osteoclasts either by impairment of osteoblasts to inhibit osteoclast differentiation or by direct transcriptional repression of RANKL in osteoclasts [Glass et al., 2005; Spencer et al., 2006].

Fig. 3 Bone remodelling

After initial activation, bone resorption is conducted by osteoclasts whereas osteoid formation provides bone-forming osteoblasts. Osteoblasts produce extracellular matrix that becomes mineralised forming new bone.

2.3 Mesenchymal stem cells

2.3.1 Multilineage potential

Stem cells are undifferentiated cells that can renew themselves as well as differentiate into specialised cell types, thereby forming new organs during embryonic development and regenerating tissue during the entire life of the organism due to normal turnover or injury [Caplan, 1991; Duplomb et al., 2007]. While totipotent embryonic stem cells can give rise to all cell types of the organism, multipotent stem cells of the adult organism, e.g. mesenchymal stem cells (MSCs), are more restricted in their differentiation potential and therefore generate only a limited number of cell types.

MSCs have been isolated from the bone marrow and various other tissues, even from some that do not originate from the mesenchymal germ layer, and show fibroblast-like morphology

[da Silva Meirelles et al., 2006]. They have been shown to differentiate into cells of various mesenchymal tissues like bone, cartilage, muscle, and adipose tissue (fig. 4) [Barry and Murphy, 2004; Caplan, 1991; Friedenstein et al., 1974; Friedenstein et al., 1976; Muraglia et al., 2000; Nöth et al., 2002a; Pereira et al., 1995; Pittenger et al., 1999; Prockop, 1997; Verfaillie, 2002]. Their differentiation and tissue regeneration potential has already been used in therapeutic approaches like tissue engineering and gene therapy [Bianco et al., 2001; Caplan, 2005].

Fig. 4 Multilineage potential of mesenchymal stem cells

Multipotent MSCs originate from pluripotent stem cells during the embryonic development and persist in the adult organism. MSCs give rise to several mesenchymal tissues as depicted. In general, increasing differentiation status correlates with decreasing proliferation.

Differentiation of MSCs requires the action of specific regulatory genes and subsequent signalling. The establishment of empirical cell culture systems that provoke adipogenic and osteogenic differentiation *in vitro* has elucidated some of the mechanisms necessary for differentiation. The key factors and processes known to be involved in adipogenic and osteogenic differentiation, respectively, are summarised below.

2.3.2 Adipogenesis

In vivo, the formation of fat cells is stimulated by hormonal inducers. The subsequent transcriptional regulation of adipogenesis has been studied by several *in vitro* models employing human and murine MSCs or pre-adipocytes and in some knockout mice. For human MSCs, a differentiation cocktail containing dexamethasone, indomethacin, 3-isobutyl-1-methylxanthine, and insulin has commonly been used to obtain adipocytes [Nöth et al., 2002a; Nuttall et al., 1998; Pittenger et al., 1999].

The induction of adipogenesis *in vitro* is considered to involve one or two rounds of clonal expansion followed by the expression of adipogenesis-specific genes and attainment of the

adipogenic phenotype [MacDougald and Mandrup, 2002; Rosen et al., 2000]. Thereby, reports on the requirement for clonal expansion have been controversial [Patel and Lane, 2000; Qiu et al., 2001; Ross et al., 2002]. Activation of gene expression is achieved by the sequential action of C/CAAT enhancer binding proteins (C/EBPs) and peroxisome proliferator-activated receptor γ 2 (PPAR γ 2) (fig. 5). Transient induction of C/EBP β and C/EBP δ provokes expression of C/EBP α and PPAR γ 2 [MacDougald and Lane, 1995; Tontonoz et al., 1994a]. Thereby, PPAR γ 2 heterodimerises with retinoid X receptor (RXR) to attain its transcriptional activity that induces transcription of C/EBP α [Rosen et al., 2000; Wu et al., 1999]. PPAR γ 2 and C/EBP α activate or enhance expression of other adipocyte-specific genes like lipoprotein lipase (LPL) acetyl CoA carboxylase, solute carrier family 2 (facilitated glucose transporter) member 4 (SLC2A4; formerly glucose transporter type 4 GLUT4), and fatty acid binding protein 4 (FABP4; formerly adipocyte P2, aP2) [Spiegelman et al., 1993].

Additionally, PPAR γ 2 activity can be increased by sterol regulatory element-binding protein 1 (SREBP1) independently from C/EBP β and C/EBP δ [Kim et al., 1998; Spiegelman et al., 1993]. Maximal PPAR γ 2 activity *in vitro* was observed after binding of coactivators, e.g. p160 proteins and CBP/p300, to PPAR γ 2 [Gelman et al., 1999; Yao et al., 1996]. Loss-of-function studies in chimeric mice and over-expression studies in non-adipogenic fibroblasts suggest that PPAR γ 2 is necessary as well as sufficient for induction of adipogenesis [Rosen et al., 1999; Tontonoz et al., 1994c], however, requirement of C/EBP α for insulin sensitivity in adipocytes has been detected [Wu et al., 1999]. Moreover, *in vivo* studies also showed an inhibitory function of PPAR γ on osteogenesis [Akune et al., 2004].

Fig. 5 Transcription factors involved in induction of adipogenic differentiation

Transient expression of C/EBP β and C/EBP δ results in expression of PPAR γ and C/EBP α , which are the key transcription factors during adipogenesis. SREBP1 augments the expression of PPAR γ and its ligands and also enhances the transcription of adipocyte-specific genes, which foster the adipogenic differentiation. Further transcription factors can promote or inhibit adipogenesis. Figure adapted from MacDougald and Mandrup [2002].

Further factors like insulin-like growth factor 1 (IGF1), macrophage colony-stimulating factor (MCSF), fatty acids, prostaglandins, and glucocorticoids have been shown to stimulate adipogenesis whereas Wnt signalling, TGF β as well as several inflammatory cytokines and growth factors have been reported to inhibit adipogenic differentiation (reviewed in MacDougald and Mandrup [2002]).

Besides endocrine signals also paracrine and/or autocrine factors are considered to regulate progression of adipogenesis (fig. 6).

At the mRNA level, terminally differentiated adipocytes are characterised by sustained expression of PPAR γ 2, LPL, and FABP4 [Ailhaud et al., 1991; Barak et al., 1999; Fried et al., 1993; Gaskins et al., 1989; Tontonoz et al., 1994b]. The fibroblast-like morphology of pre-adipocytes changes into a more rounded shape during ongoing differentiation possibly due to changes in the synthesis of cytoskeletal and extracellular matrix-associated proteins [MacDougald and Lane, 1995]. Moreover, accumulation of lipid vesicles in the cytoplasm, which contain mainly triglycerides and cholesterol esters, augments during adipogenic differentiation.

Fig. 6 Influence of paracrine and autocrine signalling on the progression of adipogenesis

Pre-adipocytes as well as adipocytes secrete factors that enhance or inhibit adipogenesis. When differentiated adipocytes exceed a critical size, they are considered to stimulate division and differentiation of pre-adipocytes either by direct stimulation (green arrows) or by inhibition of signalling pathways (blue arrow) that would otherwise inhibit adipogenesis (brown arrows). In pre-adipocytes, even autocrine signalling takes place that regulates adipogenic differentiation positively (green arrow) or negatively (brown arrow). Figure adapted from MacDougald and Mandrup [2002]. TNF α = tumour necrosis factor α .

2.3.3 Osteogenesis

The mechanisms of osteogenesis, which is crucial for bone formation, have been studied in several mouse models, osteoblast progenitor cell lines, and MSCs. *In vitro* assays use osteogenic supplements to induce differentiation. Thereby, ascorbic acid is required for accumulation of collagen type I alpha 1 (COL1A1) in the extracellular matrix of differentiating osteoblasts as well as for expression of bone gamma-carboxyglutamate (gla) protein (osteocalcin; OC) and alkaline phosphatase, liver/bone/kidney (ALP) while β -

glycerophosphate serves as exogenous phosphate source for matrix mineralisation [Franceschi and Iyer, 1992; Jaiswal et al., 1997].

At the transcriptional level, osteogenesis is induced by runt-related transcription factor 2 (RUNX2; formerly core-binding factor, runt domain, alpha subunit 1, CBFA1) and Sp7 transcription factor (SP7; formerly osterix) [Ducy et al., 2000; Ducy et al., 1997; Nakashima and de Crombrughe, 2003; Nakashima et al., 2002].

RUNX2 requires heterodimerisation with core-binding factor β (CBFB) [Kundu et al., 2002; Miller et al., 2002] to attain its transcriptional activity. Moreover, post-transcriptional regulation of RUNX2 can be conducted via phosphorylation or protein-protein interactions. For example, RUNX2 activity is augmented by mitogen-activated protein kinase (MAPK) signalling where fibroblast growth factor 2 (FGF2) has been shown to increase phosphorylation of extracellular signal-regulated kinases 1 and 2 which in turn phosphorylate RUNX2 [Jaiswal et al., 2000; Xiao et al., 2002]. In contrast, phosphorylation of two distinct conserved serine residues of RUNX2 has been reported to inhibit its heterodimerisation with CBFB and therefore to decrease osteogenesis [Wee et al., 2002].

Proteins that interact with RUNX2 and enhance its activity include hairy and enhancer of split 1 as well as SMAD1, 4, and 5 [Ito and Miyazono, 2003; McLarren et al., 2000; Zhang et al., 2000]. Other proteins like SMAD3 inhibit RUNX2 [Alliston et al., 2001; Kang et al., 2005]. Thereby, SMAD proteins are activated by transforming growth factor, beta 1 (TGF β 1), a multifunctional regulator of osteogenesis whose positive or negative effect depends on binding to different, specific receptors.

SP7 as a zinc finger-containing transcription factor is specifically expressed in osteoblasts *in vivo* [Nakashima et al., 2002]. After initiation of osteogenesis by RUNX2, SP7 is required for differentiation of pre-osteoblasts into mature osteoblasts. Furthermore, SP7 has been reported to inhibit expression of SRY (sex determining region Y)-box 9 (SOX9) which acts as a transcription factor enhancing chondrogenesis. Further transcription factors enhancing osteogenic differentiation include distal-less homeobox 5 (DLX5) that is induced by BMP signalling [Erceg et al., 2003; Miyama et al., 1999; Tadic et al., 2001] as well as a transcriptional splice variant of FBJ murine osteosarcoma viral oncogene homolog B (Δ FOSB) [Sabatakos et al., 2000].

Moreover, several hormones and signalling pathways are involved in the regulation of osteogenesis [Ebert et al., 2007]. Thereby, BMP and FGF signalling play important roles. BMP2 has been reported to enhance osteoblast commitment and can also directly influence stabilisation of RUNX2 by acetylation which in turn inhibits degradation of the transcription factor by the ubiquitination pathway [Gori et al., 1999; Jeon et al., 2006]. Together with the corresponding FGF receptors (FGFRs), several of the hitherto 22 known FGFs influence embryonic bone development as well as the osteogenic differentiation potential of adult

MSCs [Battula et al., 2007; Marie et al., 2005; Ornitz, 2005]. Special importance has been attributed to FGF2 that has been reported to modulate expression of osteogenesis-specific genes depending on the duration of its activation [Ling et al., 2006; Xiao et al., 2002]. Furthermore, FGF2 has been shown to enhance BMP2 expression resulting in enhanced RUNX2 expression and therefore accelerated osteogenesis [Choi et al., 2005]. However, FGF2 has also been reported to inhibit osteogenesis in mouse adipose tissue-derived stromal cells [Quarto and Longaker, 2006]. Since there is evidence that differential FGF receptor activation is required to propagate the sequential transit from early to late osteoblast differentiation [Jacob et al., 2006], different sets of FGF receptors might mediate the controversial effects described above.

Altogether, the onset of osteogenic differentiation can be monitored *in vitro* by increasing mRNA levels of RUNX2 and CBFB followed by increasing amounts of SP7. Pre-osteoblasts show enhanced expression of COL1A1 and ALP whereas functional osteoblasts are characterised by high expression of further osteoblast-specific genes like integrin-binding sialoprotein (bone sialoprotein; IBSP) and OC (fig. 7) [Nakashima and de Crombrughe, 2003]. Moreover, the COL1A1-rich extracellular matrix of mature osteoblasts becomes mineralised mainly by calcium and phosphate which form hydroxyapatite crystals [Currey, 1999; Hunter et al., 1996]. Thereby, induction of hydroxyapatite nucleation has been reported after addition of IBSP while other osteoblast-specific proteins like osteonectin inhibited mineralisation. Moreover, TGF β signalling has recently been shown to regulate the mineral concentration of bone matrix via SMAD3, an inhibitor of RUNX2 as already mentioned [Balooch et al., 2005].

Fig. 7 Markers of osteogenic differentiation

Osteogenic differentiation is induced in multipotent MSCs by the action of the transcription factors RUNX2 and CBFB. The resulting pre-osteoblasts already express low levels of COL1A1 (indicated by +). They require the transcriptional activity of SP7 to differentiate into mature, functional osteoblasts. Mature osteoblasts express osteoblast-specific genes, high amounts of COL1A1 (indicated by +++), and produce mineralised extracellular matrix. Figure adapted from Nakashima and de Crombrughe [2003].

2.3.4 Inverse relationship between adipogenic and osteogenic differentiation

Since osteoblasts and adipocytes share a common progenitor, the MSC, a close relationship between both differentiation pathways exists. Based on the observation that bone loss is accompanied by increasing adipose tissue in the bone marrow cavity [Beresford et al., 1992; Justesen et al., 2001; Koo et al., 1998], several factors have been reported to affect both differentiation pathways contrariwise.

Several of the lineage-specific proteins like PPAR γ 2 and Δ FOSB do not only enhance one differentiation pathway but concomitantly inhibit the other one [Akune et al., 2004; Moerman et al., 2004; Sabatakos et al., 2000]. The crucial role of PPAR γ 2 was also emphasised by the observation that rosiglitazone, a thiazolidinedione ligand of PPAR γ 2 that is employed as anti-diabetic drug for the treatment of diabetes type 2, enhanced adipogenesis and simultaneously inhibited osteogenesis *in vitro* and resulted in loss of bone mass and volume in rosiglitazone-treated mice [Ali et al., 2005; Lecka-Czernik et al., 2002; Rzonca et al., 2004]. A recent study examining short-term therapy with rosiglitazone in postmenopausal women also attributes detrimental skeletal effects to this drug [Grey et al., 2007]. Furthermore, activation or overexpression of 12/15-lipoxygenase that enzymatically generates endogenous ligands for PPAR γ 2 has been reported to enhance adipogenesis and to decrease osteogenesis *in vitro* as well as *in vivo* [Khan and Abu-Amer, 2003; Klein et al., 2004; Lecka-Czernik et al., 2002]: Thereby, the generation of a mouse strain that overexpresses 12/15-lipoxygenase provided an osteopenic phenotype whereas pharmacological inhibition of 12/15-lipoxygenase in two further mouse models of osteoporosis could improve bone mass and strength. Thus, these *in vivo* studies clearly link excess adipogenesis to phenotypes of low bone mass.

Various other signalling pathways can also determine the osteogenic and adipogenic lineage, respectively. Accordingly, members of the BMP family and further factors induced by BMP signalling inhibited adipogenesis while osteogenesis was accelerated [Gimble et al., 1995; Ichida et al., 2004; Jaiswal et al., 2000].

Another important signalling pathway promoting either the osteogenic or the adipogenic lineage is Wnt signalling that comprises 19 secreted, cysteine-rich glycosylated proteins [Logan and Nusse, 2004; Miller et al., 1999]. These glycoproteins are involved in various processes, e.g. in embryonic formation of the body plan as well as in cell growth and differentiation. Frizzled (FZD) receptors mediate their functions and induce canonical or non-canonical Wnt signalling, the mechanisms of which have not been completely elucidated yet. The activation of the FZD receptor complex in canonical Wnt signalling prevents degradation of intracellular β -catenin thereby increasing intracellular protein levels. Subsequent translocation of stabilised β -catenin into the nucleus allows for heterodimerisation with transcription factors (Lef/Tcfs) that is necessary for activation of target gene transcription.

Thereby, several Wnt proteins and Wnt co-receptors can either activate or inhibit FZD receptors. While several Dickkopf proteins have agonistic and/or antagonistic effects on Wnt signalling, secreted frizzled receptor proteins (sFRPs) represent another class of inhibitors and low-density lipoprotein receptor-related protein 5 (LRP5) enhances non-canonical Wnt signalling [Glass and Karsenty, 2007]. Whereas canonical Wnt signalling generally activates osteogenic differentiation, e.g. by direct stimulation of RUNX2 gene expression [Gaur et al., 2005], non-canonical Wnt signalling can either stimulate or diminish osteogenesis (fig. 8). In contrast to osteogenesis-accelerating LRP5- and WNT10b-correlated signalling, WNT5b disrupts this signal transduction [Bennett et al., 2002; Gustafson and Smith, 2006; Kanazawa et al., 2005; Rawadi et al., 2003]. Thereby, WNT10b and WNT5b exhibit opposing effects on adipogenesis, i.e. their activity inhibits and promotes the adipogenic lineage, respectively.

Fig. 8 Reciprocal Wnt signalling affecting osteogenic and adipogenic differentiation

Differentiation of MSCs is governed by the Wnt signalling pathway acting prior to expression of differentiation-inducing genes. Two members of Wnt signalling, i.e. WNT10b and WNT5b, have been reported to inhibit one lineage (brown arrow) while promoting the other (green arrow).

2.4 Transdifferentiation

Metaplasia or plasticity describes the conversion of one cell or tissue type into another. Thereby, this rather general term includes the conversion between undifferentiated stem cells as well as the switch between distinct differentiated cell or tissue types [Tosh and Slack, 2002]. In this work, usage of the terms ‘transdifferentiation’ or ‘reprogramming’ was restricted to describe the conversion of one “committed” or differentiated cell type into another, thereby not defining whether cells are directly switching from one phenotype to another or if dedifferentiation followed by redifferentiation is required (fig. 9). Transdifferentiation moreover challenges the conventional, hierarchical view of the differentiation process where cells developing along a distinct lineage become determined, i.e. irreversibly committed to the pathway they commenced, and progress along the lineage-specific differentiation finally forming mature phenotypes [Caplan, 1991].

Fig. 9 Models of differentiation and transdifferentiation

During differentiation, pluripotent stem cells give rise to more restricted stem cells (e.g. MSCs) that differentiate into their terminal state (e.g. functional osteoblasts) via several cell divisions and intermediate phenotypes (e.g. osteoblast progenitors). Thus, progenitor cells have been considered to represent “committed” phenotypes having passed a “point of no return”. In contrast, during transdifferentiation (reprogramming) one “committed” phenotype (e.g. (pre-)osteoblast) switches into another (e.g. adipocyte).

Nevertheless, the switch from one differentiated phenotype into another has been reported for conversion of pancreas into liver and vice versa, of myoblasts into adipocytes, and between osteoblast, adipocytes, and chondrocytes [Hu et al., 1995; Nuttall et al., 1998; Park et al., 1999; Ross et al., 2000; Song and Tuan, 2004]. However, some publications question the occurrence of transdifferentiation and rather attribute the phenotype change to cell fusion or heterogeneity of the cell population [Orkin and Zon, 2002; Terada et al., 2002; Verfaillie, 2002; Ying et al., 2002]. Indeed regarding *in vivo* experiments, fusion of bone marrow-derived stem cells with already differentiated cells of the target tissue has been reported for conversion into liver cells or into muscle cells, which are inherently capable of forming bi- and multinucleated phenotypes, respectively [Alvarez-Dolado et al., 2003; Rodic et al., 2004; Terada et al., 2002]. However, this issue is controversially discussed and does not meet our definition of a true transdifferentiation of already “committed” or differentiated cell types but rather shows plasticity of multipotential stem cells [Sato et al., 2005]. Additionally, due to the absence of differentiated cell types of another lineage *in vitro*, fusion can be excluded as a possible mechanism of metaplasia in these experiments. Regarding the criticism of possible heterogeneity, Song and Tuan [2004] even showed transdifferentiation of osteocalcin-expressing osteoblasts into adipocytes and chondrocytes, thus proving reprogramming at the single cell level and excluding heterogeneity as a reason *in vitro*.

2.5 Objective of this study

The age-related expansion of adipose tissue in the bone marrow and the concomitant loss of bone mass that is associated with diseases like osteoporosis have emphasised the requirement to further examine the correlation between the adipogenic and osteogenic differentiation pathway. Thereby, not only an impaired balance of conventional differentiation into adipocytes and osteoblasts starting from MSCs but also switching from one “committed” or differentiated phenotype into the other might contribute to the fatty degeneration.

Due to the paucity of work published hitherto regarding transdifferentiation between the adipogenic and osteogenic lineage, the present work aimed to establish a cell culture system based on human bone marrow-derived mesenchymal stem cells that would be capable of reprogramming between both lineages. Transdifferentiation of MSC-derived pre-osteoblasts and adipocytes into the respective other lineage, i.e. into adipocytes and osteoblasts, should help to elucidate the complex genetic reprogramming that was presumably required for the change of cell phenotype and function. Thus, microarray analyses were planned to examine global gene expression patterns arising shortly after initiation of adipogenic and osteogenic reprogramming. For the evaluation of regulated genes resulting from these analyses, a novel bioinformatic scoring scheme should be developed that would enable to filter out those gene products that are most likely to influence the onset of reprogramming. Finally, several of the highly ranked candidates should be addressed within functional analyses to determine their effect in differentiation and transdifferentiation events.

In summary, this study intended to

- establish a MSC-based cell culture system for adipogenic and osteogenic transdifferentiation
- examine global gene expression patterns early after initiation of transdifferentiation
- develop a novel bioinformatic scoring scheme providing the ranking of regulated genes according to their potential relevance for the onset of reprogramming
- examine the functional effect of highly-ranked gene products on differentiation and transdifferentiation.

The overall aim of this project was to identify presumable key factors of cell lineage switching, since the understanding of the underlying mechanisms of adipogenic and osteogenic reprogramming could help to develop novel therapeutic agents in the future that would not only prevent excess adipocyte formation but also stimulate osteogenesis in the bone marrow thus delaying the onset and alleviating the symptoms of age-related bone diseases.

3 Materials and methods

3.1 Materials

3.1.1 Consumables

96-well test plates	TPP, purchased from Biochrom AG, Berlin, Germany
Autoradiography films	Fuji, purchased from A. Hartenstein GmbH, Würzburg, Germany
AutoSeq G-50 columns	Amersham, purchased from GE Healthcare Europe GmbH, Munich, Germany
Blotting paper	Schleicher & Schuell, purchased from A. Hartenstein GmbH, Würzburg, Germany
Cell culture flasks (175 cm ²)	Greiner Bio-One GmbH, Frickenhausen, Germany
Cell culture flasks (25 cm ² , 75 cm ² , 150 cm ²)	TPP, purchased from Biochrom AG, Berlin, Germany
Cell strainers	BD Falcon, purchased from A. Hartenstein GmbH, Würzburg, Germany
Centrifugation tubes (15 ml, 50 ml)	TPP, purchased from Biochrom AG, Berlin, Germany
GeneChip HG-U 133A	Affymetrix UK Ltd., High Wycombe, UK
GeneChip HG-U 133 Plus 2.0	Affymetrix UK Ltd., High Wycombe, UK
Lab-Tek Chamber Slides, Permanox (2-, 4-, and 8-well)	Nunc, purchased from A. Hartenstein GmbH, Würzburg, Germany
NucleoSEQ columns	Macherey-Nagel GmbH & Co. KG, Düren, Germany
Pasteur pipettes	A. Hartenstein GmbH, Würzburg, Germany
Pipette tips	Brandt, purchased from Laug & Scheller GmbH, Kürnach, Germany
Plastic pipettes, serological	Sarstedt AG & Co., Nümbrecht, Germany
Protran nitrocellulose transfer membrane	Whatman Schleicher & Schuell, purchased from A. Hartenstein GmbH, Würzburg, Germany
Reaction tubes (1.5 ml)	Sarstedt AG & Co., Nümbrecht, Germany
Sample tubes and caps for sequencing	Applied Biosystems Applera Deutschland GmbH, Darmstadt, Germany
Short plates	Bio-Rad Laboratories GmbH, Munich, Germany
Spacer plates with integrate spacers	Bio-Rad Laboratories GmbH, Munich, Germany
Sterile filter (0.2 µm)	Carl Roth GmbH & Co. KG, Karlsruhe, Germany
UVettes	Eppendorf AG, Hamburg, Germany
3.1.2 Chemicals and reagents	
2-Mercaptoethanol	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
2-Propanol	Carl Roth GmbH & Co. KG, Karlsruhe, Germany

3-[(3-Cholamidopropyl)-dimethylammonio]-propane-sulfonate (CHAPS)	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
3-isobutyl-1-methylxanthine (IBMX)	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
Acetic acid	Merck KGaA, Darmstadt, Germany
Acetone	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
Agarose multi-purpose	Bioline GmbH, Luckenwalde, Germany
Albumin fraction V (pH 7.0)	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
Albumin from bovine serum, cell culture tested (BSA)	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany
Alizarin red S	Chroma-Gesellschaft Schmidt & Co., Stuttgart, Germany
Ammonia solution (25%)	Merck KGaA, Darmstadt, Germany
Ammonium persulfate (APS)	Carl Roth GmbH & Co. KG, Karlsruhe, Germany
Boric acid	Merck KGaA, Darmstadt, Germany
Bromophenol blue sodium salt	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany
Chloral hydrate	Mallinckrodt Baker B. V., Deventer, Netherlands
Citric acid anhydrous	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
Complete Protease Inhibitor Cocktail	Roche Diagnostics GmbH, Mannheim, Germany
Dexamethasone	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany
Dimethylsulfoxide (DMSO)	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
Dithiothreitol (DTT)	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
Dulbecco's phosphate buffered saline (PBS) powder	Biochrom AG, Berlin, Germany
Ethanol	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
Ethanol, denatured	Carl Roth GmbH & Co. KG, Karlsruhe, Germany
Glacial acetic acid	Merck KGaA, Darmstadt, Germany
Glycerol 2-phosphate disodium salt hydrate	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany
Glycerol gelatine	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany
Glycerol	Merck KGaA, Darmstadt, Germany
Glycine	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
Hematoxylin	Merck KGaA, Darmstadt, Germany
Heparin sodium salt	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany
Horse serum	PAA Laboratories GmbH, Pasching, Austria
Hydrochloric acid	Merck KGaA, Darmstadt, Germany
Indomethacin	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany
Insulin from bovine pancreas	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany

LE agarose	Biozym Scientific GmbH, Hessisch-Oldendorf, Germany
L-Ascorbic acid 2-phosphate sesquimagnesium salt	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany;
Methanol	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, Germany
N,N,N',N'-tetramethylethylenediamine (TEMED)	Merck KGaA, Darmstadt, Germany
Oilred O	Merck KGaA, Darmstadt, Germany
peqGOLD 100 bp DNA Ladder Plus	PEQLAB Biotechnologie GmbH, Erlangen, Germany
Pharmalyte (pH 3 - 10)	Amersham, purchased from GE Healthcare Europe GmbH, Munich, Germany
Ponceau S solution	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany
Potassium aluminium sulfate	Merck KGaA, Darmstadt, Germany
Rainbow marker RPN 800	Amersham, purchased from GE Healthcare Europe GmbH, Munich, Germany
Roti-Quant 5x concentrate	Carl Roth GmbH & Co. KG, Karlsruhe, Germany
Rotiphorese gel 40 (29:1) acrylamide/bisacrylamide mix	Carl Roth GmbH & Co. KG, Karlsruhe, Germany
Skim milk powder	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, German
Sodium acetate	Carl Roth GmbH & Co. KG, Karlsruhe, Germany
Sodium chloride	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, German
Sodium dodecyl sulfate (SDS)	Merck KGaA, Darmstadt, Germany
Sodium hydroxide pellets	Merck KGaA, Darmstadt, Germany
Sodium hydroxide solution (1 N)	AppliChem, purchased from A. Hartenstein GmbH, Würzburg, German
Sodium iodate	Merck KGaA, Darmstadt, Germany
Template Suppression Reagent	Applied Biosystems Applera Deutschland GmbH, Darmstadt, Germany
Thioglycolic acid	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany
Thiourea	Carl Roth GmbH & Co. KG, Karlsruhe, Germany
Triton X-100	Carl Roth GmbH & Co. KG, Karlsruhe, Germany
Urea	Carl Roth GmbH & Co. KG, Karlsruhe, Germany
WST-1 cell proliferation agent	Roche Diagnostics GmbH, Mannheim, Germany
Xylene cyanol FF	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany

3.1.3 Primers

Tab. 1 Sequences of primers used for semi-quantitative RT-PCR expression analyses

Primer sequences	T _A	Length of PCR product	Sequence ID
adipose most abundant gene transcript 1 (APM1)^a forward: 5'-GCTGGGAGCTGTTCTACTGC-3' reverse: 5'-CGATGTCTCCCTTAGGACCA-3'	59°C	233 bp	NM_004797
alkaline phosphatase, liver/bone/kidney (ALP)^a forward: 5'-TGGAGCTTCAGAAGCTCAACACCA-3' reverse: 5'-ATCTCGTTGTCTGAGTACCAGTCC-3'	51°C	454 bp	NM_000478
apolipoprotein L domain containing 1 (APOLD1)^f forward: 5'-CCAGGGGACTCGGAAGG-3' reverse: 5'-AGCAGCAGTCCCTGGAAG-3'	55°C	136 bp	NM_030817
Boc homolog (mouse) (BOC)^a forward: 5'-CGTTGGCTTCAGACCTTTGT-3' reverse: 5'-TTCATCCTTGGAGGTTCCAC-3'	55°C	222 bp	NM_033254
bone gamma-carboxyglutamate (gla) protein (osteocalcin) (OC)^a forward: 5'-ATGAGAGCCCTCACACTCCTC-3' reverse: 5'-GCCGTAGAAGCGCCGATAGGC-3'	60°C	294 bp	NM_199173

Forward and reverse sequences of primers, the annealing temperature (T_A) for each primer pair, the expected length of the PCR product, and the sequence ID (preferably the reference sequence ID, if available) of the NCBI data base are stated. Superscripts indicate the type of PCR reaction mix as follows: a = standard PCR mix, b = 2.25 mM MgCl₂, c = 3.75 mM MgCl₂, d = 2% DMSO, e = 4% DMSO, f = 6% DMSO, g = 3.75 mM MgCl₂ and 8% DMSO. Due to the existence of alternative splice variants of the dual specificity phosphatase 6 mRNA, two PCR products of different length can be generated.

3.1.4 Recombinant proteins

rhCYR61

purified at the Orthopedic Clinic, Orthopedic Centre for Musculoskeletal Research, Molecular Orthopedics and Cell Biology by Susanne Jatzke and Rita Wagemanns

rhFGF acidic = rhFGF1

R&D Systems, Wiesbaden-Nordenstadt, Germany

rhIGF-I = rhIGF1	R&D Systems, Wiesbaden-Nordenstadt, Germany
rhOPG/TNFRSF11B = rhTNFRSF11B	R&D Systems, Wiesbaden-Nordenstadt, Germany
rmSFRP2	R&D Systems, Wiesbaden-Nordenstadt, Germany

Stock solutions of lyophilized proteins purchased from R&D Systems were prepared in 0.1% BSA in PBS at concentrations of 50 µg/ml rhFGF1, 100 µg/ml rhIGF1, 50 µg/ml TNFRSF11B, and 100 µg/ml rmSFRP2. Appropriate aliquots were stored at -20°C for up to 6 months. Thawed stock solutions were stored at 4°C for up to 4 weeks. For several experiments, rhFGF1 stock solution was further diluted to 10 µg/ml after thawing and stored at 4°C for up to 4 weeks.

RhCYR61 was extracted with 3 M Tris-glycine, pH 7 from the supernatants of virus-transfected SF-21 insect cells as described [Schütze et al., 2005a] and stored at 4°C. Protein concentration was measured directly before application by micro-Bradford analysis (see chapter 3.2.4.3).

3.1.5 Antibodies

Anti-actin IgG fraction of antiserum	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany
Anti-FGF acidic antibody	R&D Systems, Wiesbaden-Nordenstadt, Germany
Anti-goat IgG-HRP antibody	R&D Systems, Wiesbaden-Nordenstadt, Germany
Anti-rabbit IgG peroxidase conjugate	Sigma-Aldrich Chemie GmbH, Schnelldorf, Germany

3.1.6 Enzymes

Amersham <i>Taq</i> DNA polymerase	GE Healthcare Europe GmbH, Munich, Germany
BIOTAQ DNA polymerase	Bioline GmbH, Luckenwalde, Germany
MangoTaq DNA polymerase	Bioline GmbH, Luckenwalde, Germany
BioScript RT	Bioline GmbH, Luckenwalde, Germany
SuperScript II RT	Invitrogen GmbH, Karlsruhe, Germany
25% Trypsin (10x concentrate)	PAA Laboratories GmbH, Pasching, Austria

3.1.7 Buffers and other solutions

Solutions for molecular biology

0.5 M EDTA, pH 8.0

19 g EDTA tetrasodium salt hydrate
ad 100 ml distilled water
pH adjusted to 8.0 and autoclaved

10% SDS

10 g sodium dodecyl sulfate
ad 100 ml distilled water

3 M Sodium acetate (pH 4.3)

24.6 g sodium acetate
ad 100 ml distilled water
pH adjusted to 4.3

10x TBE

108 g Tris base
55 g boric acid
9.05 g EDTA tetrasodium salt hydrate
ad 1 l distilled water
pH adjusted to 8.3 and autoclaved

50 mM Tris base

3.03 g Tris base
ad 500 ml distilled water
pH adjusted to 7.2 - 7.5 and autoclaved
for 10 mM Tris base diluted 1:5 with distilled water

10x Loading dye

5 mg bromophenol blue sodium salt
5 mg xylene cyanol FF
4 ml distilled water
2 ml 0.5 M EDTA, pH 8.0
3 ml glycerol
1 ml 10% SDS
The filtered solution is stored at 4°C.

Solutions for cell culture**1x PBS**

9.55 g PBS Dulbecco w/o Ca²⁺, Mg²⁺
ad 1 l distilled water
pH adjusted to 7.4 and autoclaved

1x PBS/EDTA

9.55 g PBS Dulbecco w/o Ca²⁺, Mg²⁺
0.2 g EDTA tetrasodium salt hydrate
ad 1 l distilled water
pH adjusted to 7.4 and autoclaved

2.5% Trypsin

5 ml 25% trypsin (sterile)
ad 50 ml 1x PBS

Solutions for protein preparation**Lysis buffer**

42.04 g urea
15.22 g thiourea
4 g CHAPS
0.77 g DTT
0.12 g Tris base
2 ml Pharmalyte (pH 3 - 10)
ad 100 ml distilled water and stored at 4°C.

25x Complete protease inhibitor cocktail

1 tablet Complete protease inhibitor cocktail was dissolved in 2 ml distilled water and stored in aliquots at -20°C.
Complete protease inhibitor cocktail was added to lysis buffer immediately before use to obtain a final concentration of 1x.

Solutions for staining**4% Paraformaldehyde solution**

4 g paraformaldehyde was dissolved in about 75 ml 1x PBS at 55 - 60°C under stirring for 5 min. 100 - 150 µl sodium hydroxide was added until the solution became clear. After cooling down to room temperature, the pH was adjusted to 7.4 and the solution was filled up to 100 ml with 1x PBS.

0.5% Oilred O stock solution

0.5 g Oilred O

ad 100 ml 99% 2-propanol

0.3% Oilred O working solution was prepared by mixing 6 parts stock solution with 4 parts distilled water, incubated over night and filtrated before use.

Hemalaun solution

1 g Hematoxylin

dissolved in 1 l distilled water

plus

0.2 g sodium iodate

50 g potassium aluminium sulfate

50 g chloral hydrate

1 g citrate

Solutions for SDS-PAGE**0.5% Bromophenol blue**

50 mg bromophenol blue sodium salt

ad 10 ml distilled water

10% APS

1 g ammonium persulfate

ad 10 ml distilled water

storage in aliquots at -20°C

Upper buffer

4x stock solution:

6.8 g Tris base

28.55 g glycine

2 g SDS

ad 500 ml distilled water

working solution:

100 ml 4x stock solution

84 µl thioglycolic acid

ad 400 ml distilled water

Lower buffer

10x stock solution:

15.1 g Tris base

71.4 g glycine

ad 500 ml distilled water

working solution:

100 ml stock solution

ad 1 l distilled water

Separating gel buffer = 3 M Tris base, pH 8.8

363.42 g Tris base
ad 1 l distilled water
pH adjusted to 8.8

Stacking gel buffer = 0.5 M Tris base, pH 6.8

60.57 g Tris base
ad 1 l distilled water
pH adjusted to 6.8

Sample buffer

20x stock solution:

1.2 ml 0.5 M Tris base, pH 6.8
1 ml glycerol
2 ml 10% SDS
0.5 ml 0.5% bromophenol blue
ad 9.5 ml distilled water
stored at 4°C

working solution:

950 µl stock solution
50 µl 2-mercaptoethanol

Solutions for Western blotting**0.25 M EDTA, pH 8**

9.5 g EDTA tetrasodium salt hydrate
ad 100 ml distilled water
pH adjusted to 8

5 M sodium chloride

58.44 g sodium chloride
ad 1 l distilled water

1 M Tris-HCl, pH 7.5

121.14 g Tris-base
ad 1 l distilled water
pH adjusted to 7.5 by addition of hydrochloric acid

10% Triton X-100

10 ml Triton X-100
ad 100 ml distilled water

0.1% Tween 20

999 ml 1x PBS
1 ml Tween 20

Transfer buffer

10x stock solution:

30 g Tris base
144 g glycine
ad 1 l distilled water
pH adjusted to 10 by addition of sodium hydroxide pellets

working solution:

100 ml stock solution
200 ml methanol
ad 1 l distilled water

Washing buffer I

10 ml 1 M Tris-HCl, pH 7.5
30 ml 5 M sodium chloride
8 ml 0.25 M EDTA, pH 8
10 ml 10% Triton X-100
ad 1000 ml distilled water

Washing buffer II

10 ml 1 M Tris-HCl, pH 7.5
200 ml 5 M sodium chloride
8 ml 0.25 M EDTA, pH 8
10 ml 10% Triton X-100
ad 1000 ml distilled water

The following solutions were always prepared freshly before use (amounts for 2 mini gels):

Blocking solution

1.25 g BSA
1.25 g skim milk powder
1 ml horse serum
ad 50 ml 0.1% Tween 20

Primary antibody solution

0.25 g BSA
0.25 g skim milk powder
0.25 ml horse serum
ad 25 ml 0.1% Tween 20
plus appropriate dilution of the respective primary antibodies

Secondary antibody solution

0.4 g BSA
0.4 g skim milk powder
0.4 ml horse serum
ad 40 ml 0.1% Tween 20
plus appropriate dilution of the respective secondary antibodies

Washing solution I

2 g BSA
2 g skim milk powder
2 ml horse serum
ad 200 ml washing buffer I

Washing solution II

2 g BSA
2 g skim milk powder
2 ml horse serum
ad 200 ml washing buffer II

3.1.8 Cell culture media and additives

DMEM/Ham's F-12 with L-Glutamine	PAA Laboratories GmbH, Pasching, Austria
DMEM high glucose (4.5 g/l) with L-Glutamine	PAA Laboratories GmbH, Pasching, Austria
FBS	GIBCO purchased from Invitrogen GmbH, Karlsruhe, Germany and PAA Laboratories GmbH, Pasching, Austria

Penicillin/streptomycin 100x PAA Laboratories GmbH, Pasching, Austria

stock solutions

50 mg/ml L-Ascorbic acid 2-phosphate sesquimagnesium salt

in distilled water, sterile filtered, stored in aliquots at -20°C

1 mM Dexamethasone

in ethanol, stored in aliquots at -80°C

1 M Glycerol 2-phosphate disodium salt hydrate

in distilled water, sterile filtered, stored in aliquots at -20°C

100 mM Indomethacin

in DMSO, stored in aliquots at -20°C

1 mg/ml Insulin from bovine pancreas

in 0.05% acetic acid, sterile filtered, stored in aliquots at -20°C

500 mM 3-Isobutyl-1-methylxanthine (IBMX)

in DMSO, stored in aliquots at -20°C

3.2 Methods

3.2.1 Isolation of human mesenchymal stem cells

Isolation of human MSCs was performed under the approval of the Local Ethics Committee of the University of Würzburg as well as with the informed consent of each patient, in the case of one underaged patient (10 years old) with the informed consent of the parents. Donors were aged 10 - 76 years, in average 57 ± 14 years (mean \pm standard deviation, $n = 51$). The femoral heads of patients were removed during total hip joint replacement surgery due to dysplasia-related or age-related attrition of the joint. Thereby, it was assured that none of the patients received any pharmaceuticals affecting bone metabolism.

MSCs were obtained from trabecular bone following a modified isolation protocol described previously [Nöth et al., 2002b; Schütze et al., 2005a] and originally published by Haynesworth et al. [1992]. Shortly, the cancellous bone was collected and washed once with propagation medium (see next section) by centrifugation at 1200 rpm for 5 min and discarding of the supernatant to remove any fatty components. Subsequent washing of the remaining pellet by vortexing 5 times with 10 ml propagation medium released stromal cells. Thereby, after each vortexing step, the propagation medium enriched with stromal cells was filtered through a cell strainer to hold back bone fragments and collected in a fresh tube. After final centrifugation at 1200 rpm for 5 min, the cell pellet was resuspended in a known volume of propagation medium. Cell number and vitality were determined by mixing 50 μ l cell

suspension with 50 µl Trypan blue and counting in a Neubauer counting chamber according to Lindl [2002] using the following equations:

$$\text{cell number / ml} = \frac{\text{sum of living cells}}{\text{number of counted quadrants}} \cdot 10^4 \cdot 2$$

$$\text{vitality} = \text{percentage of living cells} = \frac{\text{sum of living cells}}{\text{sum of living cells} + \text{sum of dead cells}}$$

The stromal cells were seeded at a density of more than 10^6 cells/cm² into 150 cm² or 175 cm² cell culture flasks and incubated at 37°C in a humidified atmosphere with 5% CO₂ and 95% air. About 3 days after isolation, the supernatant containing non-adherent blood cells was removed, the MSCs selected by plastic adherence were washed with PBS and further incubated in fresh propagation medium.

3.2.2 Cell culture of human mesenchymal stem cells

3.2.2.1 Culture and propagation

MSCs were cultured as described previously [Nöth et al., 2002b; Schütze et al., 2005a] in propagation medium consisting of DMEM/Ham's F-12 with L-Glutamine, 10% heat-inactivated FBS, 1x penicillin/streptomycin (final concentrations: 1 U/ml and 100 µg/ml, respectively), and 50 µg/ml L-ascorbic acid 2-phosphate. Cultures of MSCs at passage 0 usually reached confluence after 2 weeks. During this time, propagation medium was replaced every 3 - 4 days. Subsequently, cells were detached by exposure to PBS/EDTA for 10 min, addition of the same volume of 0.25% trypsin and further incubation for 2 min, both at 37°C. Addition of propagation medium inactivated the trypsin. The cells were pelleted by centrifugation (1200 rpm for 5 min), resuspended in fresh propagation medium, and the cell number and vitality were assessed.

For further propagation, cells were split at a ratio of 1:3 into new cell culture flasks. For experimental settings, MSCs of passages 0 to 3 were employed. Plating densities for these assays depended on the further applications of the cells (see next sections).

3.2.2.2 Differentiation

Differentiation of confluent MSC monolayers was started in passage 1 or 2 by incubation in the respective differentiation medium. Adipogenic differentiation medium consisted of DMEM high Glucose with L-Glutamine, 10% heat-inactivated FBS, and 1x penicillin/streptomycin additionally containing 1 µM dexamethasone, 100 µM indomethacin, 500 µM IBMX, and 1 µg/ml insulin [Pittenger et al., 1999]. For osteogenic differentiation medium, normal propagation medium was supplemented with 10 mM glycerol 2-phosphate and 100 nM dexamethasone [Jaiswal et al., 1997]. MSCs were differentiated up to 3 weeks in adipogenic medium and for up to 4 weeks in osteogenic medium. Differentiation media were replaced every 2 - 3 days.

In the course of this doctorate, the usage of DMEM high glucose instead of DMEM/Ham's F-12 as basis for the osteogenic differentiation medium was found to accelerate the efficiency of osteogenic differentiation. DMEM high glucose with L-Glutamine plus 10% heat-inactivated FBS, and 1x penicillin/streptomycin, 50 µg/ml L-ascorbic acid 2-phosphate, 10 mM glycerol 2-phosphate, and 100 nM dexamethasone was therefore applied in all experiments regarding functional testing of recombinant proteins and protein analyses.

Control samples of post-confluent MSCs were cultured in control medium consisting of DMEM high Glucose with L-Glutamine, 10% heat-inactivated FBS, and 1x penicillin/streptomycin but without differentiation factors, since cells frequently detached when propagation medium was used for post-confluent incubation.

3.2.2.3 Transdifferentiation

Transdifferentiation experiments were started in passage 0 to 2 as soon as MSCs had reached confluence. Incubation of MSCs in osteogenic differentiation medium for 5, 10, and 14 to 15 d gave rise to pre-osteoblasts that were subjected to transdifferentiation (reprogramming) into adipocytes by subsequent incubation in adipogenic medium for 14 d. Fully differentiated adipocytes, obtained after 14 d in adipogenic medium, were transdifferentiated (reprogrammed) into osteoblasts by incubation in osteogenic medium for another 28 d. In parallel with the change of medium for initiation of transdifferentiation, control samples undergoing normal differentiation obtained fresh differentiation medium of the same kind as before. Differentiation media for all samples were replaced in parallel every 2 - 3 days.

3.2.2.4 Proliferation assay

The cell proliferation reagent WST-1 enables the spectrophotometric quantification of cell proliferation. As a tetrazolium salt, WST-1 (4-[3-(4-Iodophenyl)-2-(4-nitrophenyl)-2H-5-tetrazolio]-1,3-benzene disulfonate) is cleaved by mitochondrial dehydrogenases into formazan, which is accompanied by a change of colour from slightly red to dark red. Since cell proliferation augments the activity of mitochondrial dehydrogenases, the amount of formazan dye formed is directly proportional to the metabolic activity of proliferating cells and can be quantified by measurement of the absorbance at a wavelength of 450 nm.

To examine the potential proliferative effect of rhFGF1, MSCs were seeded in subconfluent and confluent settings with 4,000 and 13,000 cells per well of a 96-well test plate, respectively. Some wells were left empty to serve as control for the absorption of the media themselves. Approximately 24 h after seeding, MSCs were exposed to various media for another 48 h as stated in tab. 2. Thereby, the control medium consisted of DMEM high Glucose with L-Glutamine, 10% heat-inactivated FBS, and 1x penicillin/streptomycin, which served as the basis for both differentiation media.

WST-1 reagent was added to each well at a final dilution of 1:10. Absorbance was repeatedly measured 15 min to 2 h after addition of WST-1 reagent. Statistical analysis was performed with Microsoft Office Excel 2002. Mean \pm SEM was calculated for each incubation condition. Mean extinction values were corrected by subtraction of the background absorbance mean value. Percentage of proliferation change was obtained by comparison of mean extinctions of specimens incubated with rhFGF1 and/or heparin to those incubated in sole control medium.

Tab. 2 Incubation conditions for proliferation assay

The proliferative effects of several incubation conditions were assessed. The number of wells per incubation condition is given for proliferation assays in a 96-well test plate. Background absorbance of the medium was determined in wells without cells.

3.2.2.5 Application of recombinant proteins in the cell culture

To assess the effects of recombinant proteins on differentiation and transdifferentiation, MSCs were plated onto Lab-Tek Chamber Slides with 4 wells at a density of 75,000 - 150,000 cells per well, respectively. When the monolayers had reached confluence one to

three days after plating, the experiments were started. The effects of several recombinant proteins on adipogenic and osteogenic differentiation as well as the effect of rhFGF1 on adipogenic transdifferentiation were tested. Concentrations of recombinant proteins were chosen according to literature describing their usage in cell culture experiments [Nakayama et al., 2006; Oshima et al., 2005; Schütze et al., 2005a; Simonet et al., 1997; Tang et al., 1996; Wesche et al., 2005]. Normal adipogenic and osteogenic differentiation, adipogenic transdifferentiation as well as post-confluent incubation in control medium (DMEM high Glucose with L-Glutamine, 10% heat-inactivated FBS, and 1x penicillin/streptomycin) were performed in parallel and served as controls.

For adipogenic differentiation, different batches of MSCs were subjected to incubation in adipogenic differentiation medium together with 50 ng/ml TNFRSF11B, 500 ng/ml rmSFRP2, 50 ng/ml rhFGF1 plus 2 U/ml heparin, 500 ng/ml rhCYR61, and 10 ng/ml rhIGF1, respectively. Thereby in all batches, one part of the cells received recombinant proteins in parallel with the adipogenic factors at confluence (at d 0), another part obtained pre-incubation of recombinant proteins at confluence in propagation medium, i.e. without adipogenic factors, 2 - 3 d before incubation with adipogenic medium further on containing the respective recombinant protein. Different concentrations of rhFGF1 (0, 6, 12, 25, and 50 ng/ml rhFGF1, each plus 20 U/ml heparin) were tested with further batches of MSCs during adipogenic differentiation with and without pre-incubation with rhFGF1 as described above. The effect of pre-incubation with rhFGF1 (0, 6, 12, 25, and 50 ng/ml rhFGF1, each plus 2 U/ml heparin) for 3 d prior to incubation in adipogenic medium without rhFGF1 was assessed. Adipogenic lineage development was assessed by Oilred O staining 0, 7, 14, and partly 21 d after addition of adipogenic factors. Another trial examined the adipogenic potential of rmSFRP2 (500 ng/ml) regarding spontaneous adipogenic differentiation in absence of other adipogenic factors. Here, Oilred O staining was performed 0, 7, 14, and 21 d after addition of rmSFRP2.

For osteogenic differentiation, MSCs were subjected to osteogenic differentiation medium in the presence of 50 ng/ml TNFRSF11B, 500 ng/ml rmSFRP2, 50 ng/ml rhFGF1 plus 2 U/ml heparin, 500 ng/ml rhCYR61, and 10 ng/ml rhIGF1, respectively. Recombinant proteins and osteogenic factors were added simultaneously. Osteogenic lineage development was monitored by ALP and Alizarin red S staining performed 0, 14 and 28 d after addition of osteogenic factors. Spontaneous osteogenic differentiation was assessed by application of potentially osteogenic TNFRSF11B (50 ng/ml) and rhFGF1 (50 ng/ml, plus 2 U/ml heparin), respectively, without further osteogenic factors. Additional controls contained 2 U/ml heparin only and 0.0005% BSA only. Here, cytochemical staining was performed 0, 14 and 28 d after addition of recombinant protein.

Moreover, the effect of rhFGF1 on adipogenic transdifferentiation was assessed. Thereby, adipogenic transdifferentiation was initiated as described in section 3.2.2.3 by incubation of pre-osteoblasts (derived from MSCs after 14 d in osteogenic differentiation medium) in adipogenic differentiation medium for another 14 d. RhFGF1 (0, 6, 12, 25 and 50 ng/ml rhFGF1 plus 2 U/ml heparin each) was added to the adipogenic medium from d 14 onwards and progress of transdifferentiation was examined compared to transdifferentiating cells not subjected to rhFGF1. Cytochemical staining of lipid vesicles was performed at the beginning of each experiment, at the time of initiation of transdifferentiation as well as 14 d afterwards. The size of areas containing lipid vesicles was semi-quantitatively measured for 6 randomly taken microphotographs of each incubation using Photoshop Elements 4.0. Thereby after 7 and 14 d of incubation, 3 and 4 independent experiments, respectively, were analysed. The significance of changes was determined by Mann-Whitney-U test.

3.2.3 Methods in molecular biology

3.2.3.1 Isolation of cellular RNA

MSCs were seeded into cell culture flasks of appropriate sizes at a ratio of 1:3. Transdifferentiation experiments were started at confluence, whereas confluent monolayers at d 0 as well as normally differentiated cells served as controls. Total cellular RNA was isolated from the controls at d 0, after 14 d, 14 d + 3 h, 14 d + 24 h, and 28 d in osteogenic medium as well as after 14 d, 14 d + 3 h, and 14 d + 24 h in adipogenic medium. Transdifferentiated RNA samples were obtained 3 h and 24 h after initiation of reprogramming as well as 14 d after adipogenic and 28 d after osteogenic transdifferentiation initiation. In additional experiments, RNA was isolated from cells transdifferentiated after 5 d and 10 d of osteogenic pre-differentiation in parallel with the respective controls (5 d and 10 d in osteogenic medium).

To isolate total RNA, the RNeasy Mini kit was used according to the manufacturer's instructions. Briefly, cell pellets were homogenised in a guanidine isothiocyanate- and β -mercaptoethanol-containing lysis buffer that inactivates RNases. Equal volumes of 70% ethanol were added to generate appropriate binding conditions before the samples were loaded onto RNeasy mini columns for centrifugation. Thereby, the RNA was bound to the silica-gel-based membranes of the columns. Possibly remaining DNA was removed by on-column digestion with DNase I. Contaminants were washed out by appropriate buffers followed by elution of purified RNA in water. Samples were stored at -80°C .

To obtain highly pure RNA specimens for application in Affymetrix microarray analyses, cell monolayers were homogenised by TRIZOL reagent directly in the culture flasks according to the manufacturer's instructions. In short, phase separation was achieved by addition of chloroform and centrifugation at 4500 rpm. For RNA precipitation, the upper aqueous phase, containing the RNA, was incubated with isopropanol and RNA was pelleted by centrifugation at 4500 rpm. The RNA pellets were subsequently resuspended in lysis buffer and purified by RNeasy Mini kit as described above.

Concentration of RNA specimens was determined by 1:25 dilution of RNA suspension in 10 mM Tris (pH 7.2 - 7.5). Absorption was measured using UV light permeable cuvettes. RNA content was determined at 260 nm, whereas extinction of 1 E_{260} corresponds to 40 $\mu\text{g/ml}$ RNA. Since proteins absorb at 280 nm and contaminants like carbohydrates and peptides absorb at 230 nm, purity of RNA was estimated by the quotients E_{260}/E_{280} and E_{260}/E_{230} . Thereby, for pure RNA E_{260}/E_{280} should be 2.0 and E_{260}/E_{230} should be larger than 2.0.

3.2.3.2 Reverse transcriptase polymerase chain reaction (RT-PCR)

RT-PCR analysis allows for detection of gene expression of specific genes in cells and tissues. After reverse transcription of total RNA into cDNA by RT, gene specific primers anneal on different strands in the DNA sequence of the gene of interest. *Taq* DNA polymerase elongates the annealed primers yielding double stranded PCR products specific for this gene.

Identical amounts of total RNA (1 - 2 μg) were reverse transcribed into cDNA using the Promega M-MLV RT, RNase H(-) point mutant, the SuperScript II RT or the Bionline BioScript RT with the respective, provided buffer system. The procedure of cDNA synthesis was performed according to the manufacturers' instructions using random hexamers in a 30 μl volume. Briefly, denaturing of secondary structures of RNA and annealing of random hexamers was achieved by heating to 70°C and subsequent chilling on ice. Reaction buffer, dNTPs, and RT were added and random hexamers were extended at 25°C prior to elongation of first strand cDNA species at 42°C . The reaction was stopped by incubation at 70°C and each specimen was diluted with HPLC water to a final volume of 50 μl .

Afterwards, PCR reactions were performed in a PTC-200 Peltier thermal cycler using cDNA specimens and gene specific primers. Amersham *Taq* DNA polymerase, BIOTAQ™ DNA polymerase or MangoTaq™ DNA polymerase were used according to the manufacturers'

instruction with the respective, provided buffer system. In short, the standard assay comprised 1x PCR buffer containing 1.5 - 1.7 mM MgCl₂, 0.3 mM dNTPs, 5 pmol forward primer, 5 pmol reverse primer, and 1 µl of cDNA in a final volume of 30 µl. Modified assays were performed with higher amounts of MgCl₂ and/or by addition of DMSO as stated in section 3.1.3. The applied PCR reaction steps are listed below.

- 1) Initial denaturing step: 94°C 3 min
- 2) Denaturing step: 94°C 45 s
- 3) Annealing step: 51 - 60°C 45 s (depending on the primer pair)
- 4) Elongation step: 72°C 1 min
- 5) Final elongation step: 72°C 3 min
- 6) Cooling step: 12°C forever

Steps 2) - 4) were repeated 22 - 48 times depending on the intensity of the band for each PCR product.

Several of the PCR primers used were already established in the laboratory, others were designed using the free online software Primer3 [Rozen and Skaletsky, 2000] (tab. 1). Whenever possible, intron-spanning primer pairs were chosen to exclude false positive detection of DNA contaminants in the RNA specimens. After optimisation of PCR reaction conditions regarding annealing temperature, cycle number as well as MgCl₂ and/or DMSO concentration, gene specificity of each primer pair was assessed by sequencing analysis of the respective PCR product (see section 3.2.3.4).

3.2.3.3 Agarose gel electrophoresis

For visualisation of PCR products and estimation of their length, specimens were applied onto agarose gels containing ethidium bromide and subjected to 1D gel electrophoresis. Ethidium bromide intercalates into double-stranded DNA or RNA and fluoresces when exposed to UV light.

1.5 - 2.0 % agarose gels were prepared by dissolving the agarose powder in 0.5x TBE buffer by boiling in a microwave. Ethidium bromide was added to the liquid agarose solution to a final concentration of 5% before the solution was filled into appropriate gel trays and combs were inserted that left behind pockets for loading of the probes. The gel polymerised during cooling to room temperature.

Equal volumes of PCR products were loaded onto the agarose-ethidium bromide gel. Thereby, PCR products obtained by use of MangoTaq™ DNA polymerase were directly loaded into the gel pockets, since the respective buffer system already contains loading dyes. The other PCR products were supplemented with 1x loading dye prior to application onto the gel. As marker for band sizes, a 100 bp DNA ladder containing DNA fragments of 100 - 3.000 bp was also loaded onto the gel. Separation of differently sized DNA markers and PCR products was achieved by application of direct current with a voltage of 0.9 V per cm² agarose gel. Thereby, negatively charged DNA fragments moved to the anode. PCR bands fluorescing due to the intercalation of ethidium bromide were visualized by exposure to UV light in a UV chamber connected to a digital camera. Photographs of the fluorescing bands were made with Irf Bio-Capt software. Densitometric evaluation of transcript amounts was performed using Irf Bio-1D software, whereas band intensities of different specimens were normalized onto those of EF1α serving as house keeping gene.

3.2.3.4 DNA sequencing

DNA sequencing allows for identification of the nucleotide order of a given DNA fragment. The chain termination method uses normal dNTPs as well as modified ddNTPs for PCR. This results in termination of DNA synthesis when a ddNTP is incorporated and therefore generates fragments of random length. Each of the different ddNTPs (ddATP, ddCTP, ddGTP, and ddTTP) is labelled with a distinct fluorescent dye that fluoresces at a different wavelength. Differently sized DNA fragments, each with a fluorescent dye at its end, are separated by electrophoresis. Fluorescence is measured at the different wavelengths and assigned to the type of ddNTP as well as the position in the DNA fragment.

In this work, specificity of PCR products was affirmed by dye terminator sequencing analyses using the Big Dye Terminator v1.1 Cycle Sequencing Kit and one of the primers by which the PCR product was generated. According to the manufacturer's instructions, a PCR mix was prepared containing 5 pmol forward or reverse primer and 1 - 2 μ l PCR product in a final reaction volume of 20 μ l. Sequencing PCR conditions are stated below.

- 1) Initial denaturing step: 94°C 4 min
- 2) Denaturing step: 94°C 30s
- 3) Annealing step: 1 min 50°C
- 4) Elongation step: 60°C 1 min
- 5) Final elongation step: 72°C 5 min
- 6) Cooling step: 12°C forever

Steps 2) - 4) were repeated 24 times.

To purify the PCR products of the sequencing PCR from salts, excess nucleotides, and primers, they were loaded onto Autoseq G50 or NucleoSeq columns according to the manufacturer's instructions. After centrifugation, these columns retained the contaminants, whereas the eluates containing the sequencing PCR products were processed. For precipitation of DNA, eluates were supplemented with 3 M sodium acetate (pH 4.3) and ethanol to obtain a final concentration of 0.1 M sodium acetate in 80% ethanol. After incubation at room temperature for 15 min and centrifugation at 13.000 rpm for 20 min, the supernatant was discarded, whereas the pellet was washed with 70% ethanol and air dried. The dried pellet was resuspended in 15 μ l Template Suppression Reagent and transferred into sample tubes for sequencing. After denaturation at 94°C for 4 min and subsequent chilling on ice, condensed water was spun down and the sample tubes were placed into the tray of the sequencer. Sequencing parameters were set with the ABI PRISM 310 collection software, sequencing analyses were performed by the Sequencing analysis 3.4 software. Obtained DNA sequences were compared to the online data base of NCBI by inserting into NCBI blast search.

3.2.3.5 cDNA microarray analysis

cDNA microarray analysis allows for large-scale expression profiling of total or messenger RNA specimens. Thereby, thousands of oligo-nucleotide probes are fixed onto a chip in certain locations and match parts of known or predicted mRNA molecules. Comparison of separate chips probed with RNA specimens obtained from differently treated cells enables estimation of gene expression differences of the distinct conditions.

Affymetrix GeneChip hybridisation, staining, and scanning of the chips as well as computation and pairwise comparison of the obtained signals were performed by PD Dr. L. Klein-Hitpass at the Institute of Cell Biology, University of Duisburg-Essen, Germany.

Total RNA specimens were used to generate double-stranded cDNA that was further employed in an *in vitro* transcription reaction that produced biotin-labelled, single-stranded cRNA. The cRNA was fragmented before hybridisation onto the GeneChips. The hybridisation cocktail containing fragmented cRNA, hybridisation controls, BSA, and herring sperm DNA was applied onto the GeneChips for 16 h. The hybridisation controls allowed for normalising between different GeneChips later on. The settings of the fluidics station, e.g. GeneChip type and sample descriptions, were controlled by the Microarray Suite 5.0 or the GeneChip Operating Software 1.2. The fluidics station conducted automated washing and staining after hybridisation. Subsequently, each GeneChip was scanned by GeneChip scanner 2500 or 3000. Thereby, the staining of hybridised cRNA by streptavidin phycoerythrin conjugate results in emission of light at 570 nm, that is proportional to the bound cRNA. The software assigned the light emission to the respective probe sets and computed their intensities. The generated data files containing the GeneChip images for each specimen were further analysed and compared pairwise by the Data Mining Tool 3.0 or 3.1.

Total RNA specimens were obtained from confluent MSCs, after 14 d + 3 h, and 14 d + 24 h of osteogenic and adipogenic differentiation as well as 3 h and 24 h after initiation of adipogenic and osteogenic transdifferentiation as depicted in figures 1 and 2. Cell culturing

and RNA isolation were performed as described in sections 3.2.2.1, 3.2.2.2, and 3.2.3.1. RNA specimens of transdifferentiated samples were compared to (pre)differentiated controls, whereas sample and control specimens were taken at the same time points, i.e. 3 h and 24 h after initiation of transdifferentiation and after continuing with differentiation, respectively. For adipogenic transdifferentiation, one first microarray was conducted using the 4 of the smaller GeneChips HG-U 133A that can detect 14,500 genes. Two further microarray experiments for adipogenic transdifferentiation and two microarray experiments for osteogenic transdifferentiation employed altogether 16 of the more complete GeneChips HG-U 133 Plus 2.0 that can detect 38,500 genes.

Thus, comparison of the expression profiles of transdifferentiated cells to those of (pre)differentiated ones allowed for detection of differentially expressed probe sets. In doing so, only those probe sets were stated as differentially regulated that fulfilled the following criteria: increase or decrease call according to change p-values of ≤ 0.001 or ≥ 0.999 in at least one of the compared signals and signal \log_2 ratio ≤ -1.32 or ≥ 1.32 for GeneChips HG-U 133A or signal \log_2 ratio ≤ -1 or ≥ 1 for GeneChips HG-U 133 Plus 2.0, respectively. The logarithmic ratio corresponds to at least 2.5-fold changes in gene expression for the smaller GeneChips and at least 2-fold changes in gene expression for the larger GeneChips, whereas negative values indicate a decrease and positive values indicate an increase of gene expression in transdifferentiated samples compared to the respective (pre)differentiated control.

Gene ontology (GO) analyses regarding differentially regulated genes were performed using the online tools of the Affymetrix NetAffx analysis Center and the GOstat analysis software developed by Beissbarth and Speed [2004]. The latter analyses were performed by PD Dr. L. Klein-Hitpass applying the Benjamini and Hochberg correction [Benjamini and Hochberg, 1995]. Thereby, all probe sets of the respective applied GeneChip that exhibited at least one P detection call in the compared samples for each of the repeated experimental sets served as reference.

Further information regarding individual gene products was supplied by the Invitrogen iPath tool or from the GeneCards website.

3.2.4 Methods in protein analysis

3.2.4.1 Preparation of intracellular protein

To examine gene expression profiles not only at the mRNA level, protein was extracted from MSCs at the day of confluence (d 0), after 14 d of adipogenic and osteogenic differentiation as well as 1, 2, and 3 d after initiation of adipogenic and osteogenic transdifferentiation, respectively. Therefore, cell monolayers were detached and pelleted at the indicated time points from cell culture flasks as described in chapter 3.2.2.1.

Cell pellets were lysed in at least 500 μ l lysis buffer with Complete protease inhibitor cocktail and sonified. Centrifugation at 1200 rpm for 10 min was performed to clear the supernatant containing the protein, which was aliquoted and stored at -80°C .

For one batch of MSCs, intracellular protein was isolated in parallel with total RNA using the NucleoSpin RNA/Protein kit according to the manufacturer's instruction. In short, cell pellets were dissolved in lysis buffer, which inactivated RNases and proteases present in the samples. After filtration of each lysate, RNA and DNA were bound to the silica membrane of NucleoSpin RNA/Protein columns by centrifugation, whereas the protein was collected with the flow-throughs. Washing of the columns with membrane desalting buffer prepared the columns for subsequent DNA digestion by rDNase I. After 3 washing steps that inactivated the DNase and removed any contaminants, the RNA was eluted in RNase-free water and stored at -80°C in aliquots. Protein-containing flow-throughs were mixed with protein precipitator, incubated at room temperature and centrifuged. The supernatants were discarded, the pellets were washed with 50% ethanol, dried at room temperature, and dissolved in 100 μ l protein loading buffer containing reducing agent at 96°C to denature all proteins. After cooling down to room temperature, samples were cleared by centrifugation and supernatants were stored in aliquots at -20°C .

3.2.4.2 Protein precipitation in culture supernatants

Additional protein samples were prepared from culture supernatants of MSC monolayers at confluence (d 0), after 14 and 17 d of adipogenic and after 14, 17, and 28 d of osteogenic differentiation as well as 3 d after initiation of adipogenic and osteogenic transdifferentiation, respectively. To reduce contamination by serum proteins, 2 d prior to harvesting of the supernatants, the cell monolayers were incubated in propagation medium and differentiation medium, respectively, that contained only 0.5% heat-inactivated FCS instead of 10% (compare section 3.2.2).

Precipitation of proteins was achieved by vortexing of the supernatants with the 4-fold volume of pre-chilled acetone and incubation at -20°C for at least 1 h. After centrifugation at 4500 rpm and 4°C for 10 min, the supernatants were discarded whereas the pellet was air dried for 5 min and resolved in at least 500 µl lysis buffer with Complete protease inhibitor cocktail. Aliquots of protein samples derived from cell culture supernatants were stored at -80°C.

3.2.4.3 Determination of protein concentration

Due to its adhesive nature rhCYR61 protein tends to precipitate during storage at 4°C. Therefore, concentrations of the protein preparations were determined prior to each application in (trans)differentiation assays using the Micro-Bradford method. Based on the method established by Bradford [1976], Roti-Quant 5x contains the dye Coomassie brilliant blue-G250, which can exist in 3 states absorbing at separate wave lengths. Binding to protein molecules transfers the dye from the cationic into the anionic state. Protein concentration is widely proportional to the change of absorption due to the switch to the anionic state, which is measured at 595 nm.

In particular, calibration standards of 25, 50, 75, 100, 150, and 250 µg/ml BSA in 100 mM glycine and 1x Roti-Quant working solution diluted in distilled water were prepared. Thereby, standards were diluted in the same solution as used for elution of protein during preparation. To obtain a calibration curve, 10 µl 100 mM glycine (as blank) and 10 µl of each calibration standard (25 - 250 µg/ml BSA) were vortexed and measured in duplicates. Protein samples were measured analogously after mixing of 10 µl protein samples in 500 µl volumes of Roti-Quant working solution. Measurement of absorption was conducted 5 to 30 min after preparation of the dye-protein mixes in ½ micro cuvettes at 595 nm in a photometer that also calculated absolute protein concentrations according to the obtained calibration curve.

Protein concentration of cell lysates and protein solutions obtained from cell culture supernatants could not be determined by the Bradford method, because the lysis buffer used to solve these proteins contained disturbing compounds, e.g. high amounts of CHAPS, urea, thiourea, and DTT that would also bind to or reduce the dye. Hence, the Plus One 2D-Quant kit was used according to the manufacturer's instruction. Briefly, protein of BSA calibration standards containing 10, 20, 30, 40, and 50 µg protein as well as of 5 - 10 µl of protein samples to be measured were prepared in duplicates and quantitatively precipitated under addition of the appropriate reagents by centrifugation. Protein pellets were resolved in a copper-containing solution shortly before addition of the colour reagent working solution, whereas copper ions could bind to the proteins. Copper solution plus colour reagent working solution served as blank. Since the colorimetric agent binds to unbound copper, changes of its absorption are inversely related to protein concentration. The mixes were transferred into ½ micro cuvettes and absorption was measured 15 - 60 min after addition of the colour reagent at 480 nm in a photometer that generated the calibration curve due to absorption of standards and calculated absolute amounts of protein for the initially applied protein solution volume.

3.2.4.4 SDS-polyacrylamide gel electrophoresis (SDS-PAGE)

SDS-polyacrylamide gel electrophoresis is applied to separate a mix of denatured proteins obtained from cell lysates or cell culture supernatants by their mass. Thereby, the sample buffer containing 2-mercaptoethanol as a reducing agent and SDS as a detergent linearise

the proteins. Moreover, the latter charges the proteins negatively by binding to disulfide linkages of the amino acids, whereas the amount of this negative charge is proportional to the protein mass. Hence, application of a direct current results in migration of proteins across the gel towards the anode with different velocities and therefore proteins are separated due to their mass.

The gel consists of two compartments differing in acrylamide concentration and pH. The small upper area is formed by the stacking gel with lower acrylamide concentration that allows for an even accumulation of protein samples loaded into the pockets located in this compartment. The lower area consists of the separating gel with higher acrylamide concentration where differently sized proteins are resolved during electrophoresis. The compositions of both gels are stated in tab. 3.

Tab. 3 Composition of SDS-acrylamide gels

	5% stacking gel	12.5% separating gel
distilled water	2.4 ml	4.8 ml
Rotiphorese gel 40 (29:1) acrylamide/bisacrylamide mix	0.5 ml	3.75 ml
stacking gel buffer	1 ml	–
separating gel buffer	–	1.25 ml
10% SDS	0.04 ml	0.1 ml
TEMED	0.004 ml	0.004 ml
10% APS	0.04 ml	0.1 ml

Volumes are given for preparation of 2 mini gels. TEMED and APS were added not until immediately before use of the mixture since these compounds act as radical starters for gelling.

After cleaning with 70% denatured ethanol, one short glass plate and one spacer glass plate with integrated spacers were put together for each gel, clamped into special fasteners, and fitted onto a special rack for gel casting. Thus, the bottom and both lateral rims of the plates were sealed. First, the separating gel was cast between the plates filling about $\frac{2}{3}$ of the space and covered with 2-propanol. After polymerisation of the separating gel, 2-propanol was removed and the stacking gel was poured on it. Combs were inserted for the later pockets and polymerisation was awaited. Together with the glass plates serving as gel trays, the mini gels were carefully removed from the fasteners and fitted into a mini electrophoresis cell designed to hold 2 mini gels, which was inserted into a mini buffer tank. Upper buffer was filled between the gel trays up to their upper rim and combs were removed. Lower buffer was filled into the mini buffer tank up to the bottom of the gel trays.

Equal quantities of protein samples were diluted with distilled water to a final volume of 10 μ l. After mingling with 10 μ l sample buffer, samples were incubated for 5 min at 80°C and subsequently for 5 min on ice. 20 μ l sample per lane were loaded onto the gels, as size standard 10 μ l rainbow marker were applied. The mini buffer tank was covered with its lid and direct current was applied at a voltage of 190 V for about 30 min. Progression of sample migration was controlled by location of bromophenol blue included in the sample buffer and by resolving of the coloured rainbow marker bands. Mini gels were then employed for western blotting.

3.2.4.5 Western blotting

Western blotting, also called immunoblotting, is a method to detect distinct proteins in a given sample and to compare the amounts of this protein between several samples. Previously, by SDS-PAGE separated proteins are transferred to a membrane, where they are accessible to detection by protein specific antibodies that link them to reporter enzymes that allow for their visualisation.

For the assembly of the western blot, blotting paper as well as nitrocellulose membrane were soaked with transfer buffer. Placed on the bottom plate electrode of the blotting chamber, 3 layers of blotting paper, the nitrocellulose membrane, the gel, and another 3 layers of blotting paper were assembled into a stack in this order. The upper plate electrode was placed on top and a direct current of 150 mA per membrane was applied for 2 - 3 h. Proteins were blotted onto the nitrocellulose membrane due to migrating according to their negative charge towards the anode (bottom electrode). Efficiency of blotting was controlled by incubating the nitrocellulose membrane for 10 min in Ponceau S solution that reversibly stains all protein bands on the membrane but is much less sensitive than detection by antibodies. After short washing in distilled water, red protein bands were visible. Subsequent agitation in blocking solution for 2 h not only washes out the Ponceau S but also inhibits non-specific binding of the antibodies to the membrane. Incubation with the primary antibody solution containing 1:100 anti-FGF1 and 1:5000 anti-actin was performed over night at 4°C. After washing the membrane 4x 15 min in washing solution I, it was further agitated for 1 h in the secondary antibody solution containing 1:2000 anti-rabbit IgG and 1:2000 anti-goat IgG, both labelled with horseradish peroxidase as reporter enzyme. 4x 15 min washing with washing solution II prepared the membrane for detection of bound antibodies by using the ECL Plus kit that contains the Lumigen PS-3 acridan substrate. This substrate is converted into acridinium ester intermediates by the horseradish peroxidase activity of the antibodies. The intermediate compound reacts with peroxide also contained in the kit resulting in the emission of light that can be detected on an autoradiography film.

According to the manufacturer's instructions, each membrane was exposed to the ECL Plus reagents for several min. After removing of the solution, the membranes were wrapped into cling film and placed in an X-ray film cassette. 2 autoradiography films were applied on each membrane in a dark room, one exposed for 2 min the other for up to 1 h. The first film was immediately developed to estimate the appropriate exposure time for the second one. Proteins detected by the primary antibodies emerged as dark bands, the size standard was copied by overlaying on the respective nitrocellulose membrane.

3.2.5 Cytochemical methods

For staining of cell monolayers, MSCs were seeded onto 2-well or 4-well Lab-Tek Chamber Slides at densities of 150,000 - 300,000 (2-well) and 75,000 - 150,000 cells (4-well) per well resulting in confluence 1 - 2 d after seeding. Staining of monolayers for osteogenic and adipogenic markers was performed at the day of confluence and during (trans)differentiation depending on the incubation condition (7, 14, 28, and 42 d after starting of the experiment).

3.2.5.1 Alizarin red S staining

Alizarin red S staining of Ca_2HPO_4 deposition typically for mineralised extracellular matrix of (pre-)osteoblasts was performed as described previously [Laczka-Osyczka et al., 1998]. Briefly, 1% Alizarin red S dye dissolved in 0.25% ammonia water served as staining solution. Cell monolayers were washed with 1x PBS, fixed for 10 min in ice cold methanol, washed with distilled water, and incubated for 2 min in the Alizarin red S staining solution. Excess dye was removed by repeated washing with distilled water prior to embedding with glycerol gelatine. Stained areas appeared dark red to red brown.

3.2.5.2 Alkaline phosphatase (ALP) staining

Staining of cytoplasmic ALP was performed as indicator for osteogenic development by using Alkaline Phosphatase, Leukocyte Kit 86-C according to the manufacturer's instruction but without counterstaining of cell nuclei. Briefly, culture medium was pipetted off thoroughly and cell monolayers were fixed for 30 s by citrate-acetone-formaldehyde solution. After washing with distilled water, staining for ALP activity was performed by incubation for 15 min in an alkaline diazonium salt solution containing sodium nitrite, naphtol, and Fast blue BB. The latter provided blue staining of cells containing active ALP. After washing with distilled water, cell monolayers were embedded in glycerol gelatine.

3.2.5.3 Oilred O staining

Oilred O staining was employed to stain intracellular lipid vesicles, which are generated during adipogenic development. As described previously by Pittenger et al. [1999], cell monolayers were washed with PBS, fixed in 4% paraformaldehyde solution for 10 min, and washed with distilled water. After 5 min incubation in 60% 2-propanol, cell monolayers were stained with filtered Oilred O working solution for 10 min. After washing with 60% 2-propanol and distilled water, cell nuclei were counterstained by incubation in hemalaun for 2 min and subsequent blueing by thorough rinsing in tap water. Intracellular lipid vesicles stained light orange to red.

4 Results

4.1 Adipogenic and osteogenic differentiation potential of human mesenchymal stem cells

Adipogenic and osteogenic differentiation of human MSCs was achieved by incubation of confluent monolayer cultures with differentiation-inducing supplements as described previously [Nöth et al., 2002a]. Adipogenic and osteogenic differentiation were monitored by determination of mRNA levels of adipogenic (PPAR γ 2 and LPL) and osteogenic markers (ALP and OC). Additionally, cytochemical staining analyses were performed that detected adipogenesis-specific accumulation of intracellular lipid vesicles (Oilred O staining) and osteogenesis-specific ALP activity as well as deposition of mineralised extracellular matrix (Alizarin red S staining) [Aubin, 1998; Pittenger et al., 1999; Rosen et al., 2000; Stein et al., 1996].

While undifferentiated, confluent monolayers did not express lineage specific markers, these markers were present during the respective differentiation assays (fig. 10). The osteogenic markers ALP and OC augmented during osteogenic incubation. ALP mRNA was detected from day 10 onwards with increasing levels, OC mRNA levels were highest after 10 d and 15 d of osteogenic differentiation. After 28 d of osteogenic differentiation, also weak expression of adipogenic markers was observed at the mRNA level. After 14 d of adipogenic differentiation, the lineage-specific markers PPAR γ 2 and LPL were expressed, whereas only very small amounts of ALP mRNA were detected.

Cytochemical staining further confirmed the osteogenic and adipogenic differentiation potential of the employed MSCs. In accordance to the mRNA levels of ALP, only few cells of the confluent, undifferentiated monolayer showed ALP activity, whereas ALP activity steadily extended during osteogenic differentiation homogeneously over the monolayer (fig. 11). Distinct calcium hydrogen phosphate deposition in the extracellular matrix stained by Alizarin red S was detected from day 14 onwards (fig. 12). During adipogenic differentiation, the amount and the size of lineage-specific intracellular lipid vesicles stained by Oilred O were increased (fig. 13).

Hence analysis of lineage-specific mRNA levels as well as cytochemical staining of lineage-specific markers, proved differentiation of MSCs into osteoblasts after 28 d of osteogenic incubation and into adipocytes after 14 d of adipogenic incubation as previously shown [Schütze et al., 2005b].

Fig. 10 Gene expression during osteogenic and adipogenic differentiation

MSCs were subjected to osteogenic and adipogenic incubation at day 0, when the undifferentiated monolayer had reached confluence. As stated, MSCs were incubated for up to 28 d in osteogenic differentiation medium and for 14 d in adipogenic medium, respectively. RNA was isolated at the given time points. RT-PCR analyses for osteogenic (ALP, OC) and adipogenic markers (PPAR γ 2 and LPL) were performed while mRNA levels of the house keeping gene EF1 α served as internal controls. The figure depicts the representative expression patterns under the described conditions. diff. = differentiation.

Fig. 11 ALP staining during osteogenic differentiation

Representative staining of ALP activity (in blue) is displayed for undifferentiated MSCs (A) and during the course of osteogenic differentiation, i.e. after 7 d (B), 14 d (C), and 28 d (D) of osteogenic incubation. Scale bar = 100 μ m.

Fig. 12 Alizarin red S staining during osteogenic differentiation

Representative staining for mineralised extracellular matrix (in red) in undifferentiated MSCs (A) as well as in monolayers incubated for 7 d (B), 14 d (C), and 28 d (D) in osteogenic medium. Scale bar = 100 μ m.

Fig. 13 Oilred O staining during adipogenic differentiation

Representative staining for intracellular lipid vesicles (in orange) in undifferentiated MSCs (A) as well as monolayers incubated for 7 d (B) and 14 d (C) in adipogenic medium is depicted. Cell nuclei were counterstained with hemalaun and appear blue. Scale bar = 100 μ m.

4.2 Adipogenic and osteogenic transdifferentiation potential of human mesenchymal stem cells

The confirmation of the adipogenic and osteogenic differentiation potential of MSCs applied in our cell culture system served as prerequisite for the examination of the transdifferentiation potential of these MSCs. Thereby, transdifferentiation was initiated by switching to the respective other differentiation medium as depicted in fig. 14 and fig. 15. The same means as for differentiation were employed to monitor the transdifferentiation processes, i.e. analysis of mRNA levels of lineage-specific marker genes as well as lineage-specific cytochemical staining.

Fig. 14 Model of adipogenic transdifferentiation

MSCs were differentiated into osteoblast progenitors prior to adipogenic transdifferentiation (light red box). Control samples were further on incubated in fresh osteogenic medium, i.e. conventionally differentiated into osteoblasts.

Fig. 15 Model of osteogenic transdifferentiation

MSCs were differentiated into adipocytes prior to osteogenic transdifferentiation (light blue box). Control samples were further on cultured in fresh adipogenic medium.

4.2.1 Adipogenic transdifferentiation

The adipogenic transdifferentiation potential of pre-osteoblasts obtained after up to 15 d of osteogenic incubation was assessed, since these pre-osteoblasts expressed osteogenic markers but no adipogenic ones unlike fully differentiated osteoblasts that additionally showed weak expression for adipogenesis-specific LPL and PPAR γ 2 mRNA (fig. 16). The duration of osteogenic pre-incubation of 5 d, 10 d, and 14 d/15 d was chosen arbitrarily to vary the pre-differentiation period examining its potential influence on the transdifferentiation capability. The pre-osteoblasts were subjected to reprogramming by incubation in adipogenic differentiation medium for another 14 d, i.e. for the same period of time that is necessary for conventional adipogenic differentiation starting from MSCs.

This assay resulted in strong expression of adipogenic marker mRNAs (LPL and PPAR γ 2) whereas osteogenic marker mRNA levels declined (ALP) or expression was even not detectable any more (OC) (fig. 16). Thereby, the duration of pre-incubation did not affect the transdifferentiation capability of the cells. Due to this observation, only monolayers subjected

to 14 d of osteogenic pre-differentiation were employed and incubated for another 14 d in adipogenic medium prior to the analysis of lipid vesicle formation by Oilred O staining. As for conventionally differentiated, MSC-derived adipocytes (fig. 17 A), the transdifferentiated cells (fig. 17 B) accumulated intracellular lipid vesicles that were homogeneously distributed over the monolayer. This shows that in our cell culture system, pre-osteoblasts were capable of adipogenic transdifferentiation resulting in an adipogenic phenotype.

Fig. 16 Gene expression after adipogenic transdifferentiation

MSCs were subjected to osteogenic and adipogenic incubation at day 0, when the undifferentiated monolayer had reached confluence. As stated, MSCs were incubated for up to 28 d in osteogenic differentiation medium and for 14 d in adipogenic medium, respectively. After 5, 10, and 14 d/15 d of osteogenic pre-differentiation, further samples were transdifferentiated by application of adipogenic medium for another 14 d as stated. RNA was isolated at the given time points. RT-PCR analyses for osteogenic (ALP, OC) and adipogenic markers (PPAR γ 2 and LPL) were performed while mRNA levels of the house keeping gene EF1 α served as internal controls. The figure representatively displays changes in marker gene expression under the stated incubation conditions. diff. = differentiation.

Fig. 17 Oilred O and Alizarin red S staining of (trans)differentiated MSCs

Fully differentiated adipocytes (A; 14 d in adipogenic medium) as well as transdifferentiated adipocytes (B; 14 d in osteogenic medium plus 14 d in adipogenic medium) were stained by Oilred O for intracellular lipid vesicles that appear orange whereas cell nuclei counterstained with hemalaun appear blue. Fully differentiated osteoblasts (C;

28 d in osteogenic medium) and transdifferentiated osteoblasts (D; 14 d in adipogenic medium plus 14 d in osteogenic medium) were stained for mineralised extracellular matrix by Alizarin red S appearing red. Arrows in D point at residual lipid vesicles. The figure represents the general phenotypes generated under the applied conditions. Scale bar = 100 μ m.

4.2.2 Osteogenic transdifferentiation

To assess the osteogenic transdifferentiation potential, fully differentiated adipocytes obtained after 14 d of adipogenic incubation were subjected to reprogramming into osteoblasts by further incubation in osteogenic differentiation medium for another 28 d, i.e. for the same period of time that is necessary for conventional osteogenic differentiation starting from MSCs. Here, shorter durations of adipogenic incubation prior to initiation of transdifferentiation were not examined, since only fully differentiated adipocytes showed distinct accumulation of lipid vesicles (fig. 13).

In this assay, strong expression of osteogenic marker mRNAs (ALP and OC) was detected 28 d after initiation of transdifferentiation but also adipogenic marker mRNAs (LPL and PPAR γ 2) were still expressed (fig. 18). Transdifferentiated monolayers stained positive for mineralised extracellular matrix (fig. 17 D) like fully differentiated osteoblasts obtained from MSCs (fig. 17 C). This confirmed the osteogenic reprogramming, but in accordance to the results at the mRNA level, residual lipid vesicles were also detectable in the monolayers of transdifferentiated samples. This shows that at least in part our cell culture system allows for osteogenic transdifferentiation of fully differentiated adipocytes resulting in the development of an osteogenic phenotype.

Fig. 18 Gene expression after osteogenic transdifferentiation

Prior to RNA isolation, MSCs were incubated in adipogenic medium for 14 d and in osteogenic medium for 28 d, respectively, as stated. Further samples of fully differentiated adipocytes (14 d in adipogenic medium) were transdifferentiated into osteoblasts by incubation in osteogenic differentiation medium for another 28 d before RNA was isolated. Representative results of RT-PCR analyses for osteogenic (ALP, OC) and adipogenic markers (PPAR γ 2 and LPL) are depicted while mRNA levels of the house keeping gene EF1 α served as internal controls. diff. = differentiation.

4.3 Affymetrix microarray analyses of adipogenic and osteogenic transdifferentiation

RNA specimens isolated shortly after initiation of adipogenic and osteogenic transdifferentiation were employed for cDNA microarray analyses. Thereby, the time points of RNA isolation were chosen arbitrarily 3 h and 24 h after initiation of transdifferentiation to detect gene regulation in the early stage of reprogramming.

4.3.1 Regulation of gene products shortly after initiation of transdifferentiation

4.3.1.1 Affymetrix GeneChip HG-U 133A

In a first attempt, RNA specimens isolated during adipogenic transdifferentiation (fig. 19) were compared to further on in osteogenic medium incubated osteoblast progenitors using the Affymetrix GeneChip HG-U 133A that was able to detect regulation of about 14,500 genes.

Fig. 19 Time points for microarray analyses during adipogenic transdifferentiation

Osteoblast progenitors were subjected to adipogenic transdifferentiation (samples; red box) as well as to osteogenic differentiation (controls). RNA specimens isolated 3 h and 24 h after initiation of the reprogramming from transdifferentiated samples as well as from normally differentiated controls were applied for microarray analyses. Thereby, transdifferentiated samples were compared to their respective differentiated control isolated at the same time point.

The comparison of transdifferentiating osteoblast progenitors with osteoblast progenitors that continued with normal differentiation yielded 258 at least 2.5-fold regulated probe sets corresponding to 202 gene products. Detailed distribution of regulated probe sets regarding the time points of RNA isolation are shown in fig. 20. In the appendix, tab. 12 and tab. 13 list regulated probe sets due to their degree of regulation (fold change) from highest up-regulation to highest down-regulation. Amongst the regulated genes, only three

adipogenesis-associated genes were detected to be up-regulated 24 h after initiation of transdifferentiation: LPL (3.1-fold and 3.6-fold in 2 different probe sets), C/EPB α (10.5-fold), and FABP4 (14.5-fold). None of the other established adipogenesis- or osteogenesis-related markers showed differential expression early during adipogenic transdifferentiation within the examined 24 h time frame.

Fig. 20 Numbers of regulated genes during adipogenic transdifferentiation – microarray analysis with GeneChips HG-U 133A

The number of at least 2.5-fold regulated genes is stated for the microarray experiment employing the smaller Affymetrix GeneChips HG-U 133A for adipogenic transdifferentiation. The Venn diagram (A) shows the distribution of regulated genes according to the time points of RNA isolation, thereby the intersection displays the number of genes regulated at both time points examined. Discrimination between numbers of up- and down-regulated genes for both time points is depicted in B.

4.3.1.2 Affymetrix GeneChip HG-U 133 Plus 2.0

Since in the meantime the more complete Affymetrix GeneChip HG-U 133 Plus 2.0 was available, further microarray analyses were conducted by usage of these GeneChips that were able to detect gene regulation of 38,500 genes. Moreover, both transdifferentiation directions were assessed. Thereby, analyses for each transdifferentiation direction were performed in duplicates employing different MSC charges. Again, transdifferentiated RNA samples were compared to those obtained from normally differentiated cells (fig. 19 and fig. 21). Since the microarray analysis for each transdifferentiation direction was performed in duplicates, only those genes were taken into account that exhibited the same regulation pattern in the repeated microarray analyses using different charges of MSCs while the amount of regulation was at least 2-fold. For adipogenic transdifferentiation, the analyses resulted in 414 reproducibly regulated genes whereas 922 reproducibly regulated genes were detected for osteogenic transdifferentiation. Fig. 22 displays the distribution of regulated

genes according to the time points after initiation of transdifferentiation as well as the number of up- and down-regulated genes for each transdifferentiation pathway. In the appendix, all at least 2-fold regulated probe sets (tab. 14, tab. 15, tab. 16, and tab. 17) are listed.

Fig. 21 Time points for microarray analyses during osteogenic transdifferentiation

Fully differentiated adipocytes were subjected to osteogenic transdifferentiation (samples; blue box) as well as to adipogenic differentiation (controls). RNA specimens isolated 3 h and 24 h after initiation of the reprogramming from transdifferentiated samples as well as from normally differentiated controls were applied for microarray analyses. Thereby, transdifferentiated samples were compared to their respective differentiated control isolated at the same time point.

Fig. 22 Numbers of reproducibly regulated genes during transdifferentiation – microarray analyses with GeneChips HG-U 133 Plus 2.0

For adipogenic as well as for osteogenic transdifferentiation, the numbers of reproducibly and at least 2-fold regulated genes are stated for the microarray experiments employing the more complete Affymetrix GeneChips HG-U 133 Plus 2.0. The Venn diagrams (A) depict the distribution of regulated genes according to the time points of RNA isolation. Thereby the intersection displays the number of genes regulated at both time points examined. The graph in B shows the discrimination between numbers of up- and down-regulated genes for both time points and both transdifferentiation directions (OB into AC = adipogenic transdifferentiation and AC into OB = osteogenic transdifferentiation).

4.3.2 Re-evaluation of microarray data by semi-quantitative RT-PCR

The results of differential gene regulation obtained by Affymetrix array analyses employing the small as well as the larger GeneChips were re-evaluated by semi-quantitative RT-PCR after establishment of the respective PCR reactions.

For the first microarray analysis that employed the smaller Affymetrix GeneChips and only examined one charge of adipogenic transdifferentiation, a selection of 22 regulated genes was assessed by densitometric evaluation of RT-PCR bands on agarose gels. These genes were chosen due to their high fold changes obtained by microarray analysis and under consideration of their functional properties that could be potentially relevant during adipogenic transdifferentiation. Re-evaluation by RT-PCR that employed the same RNA samples as for the microarray resulted in accordance of regulation for 20 of 22 genes products (tab. 4 and tab. 5). 3 h after initiation of adipogenic transdifferentiation, 10 of 11 gene products that should be regulated according to the microarray analysis were confirmed (tab. 4). 24 h after initiation of adipogenic transdifferentiation, 11 of 12 genes were in accordance with the microarray data (tab. 5). One of the two genes whose regulation could not be confirmed by RT-PCR encoded for a gene without known function (APOLD1, formerly hypothetical protein DKFZp434F0318) the other one was a hypothetical gene (MGC4655). Taking RNA samples from two additional MSC charges subjected to adipogenic transdifferentiation and comparing their gene regulation with the microarray data resulted in accordance for 16 of the above 20 confirmed gene regulations in at least one of the two additional RNA samples, 9 of these genes even matched the microarray results for both additional transdifferentiation experiments (tab. 4 and tab. 5).

Tab. 4 Accordance of microarray data and RT-PCR analyses 3 h after initiation of adipogenic transdifferentiation – GeneChips HG-U 133A

Gene name (gene symbol)	Identical RNA probes			Additional RNA probes		
	Fold change		Accordance with microarray data	Fold change		Number of accordances with microarray data
	Micro-array analysis	RT-PCR analysis		1 st additional RT-PCR analysis	2 nd additional RT-PCR analysis

Microarray data and densitometric evaluation of fold changes of gene regulation 3 h after initiation of adipogenic transdifferentiation. Thereby, positive values indicate fold change of up-regulation whereas negative values state fold change of down-regulation of gene expression. In the column 'microarray analysis', multiple values per gene product represent fold changes of different probe sets detecting the same gene. Accordance between microarray analysis and RT-PCR analysis was assessed under the following criteria:

- + same algebraic sign and $-2.0 < \text{fold change} \leq -1.2$ or $1.2 \leq \text{fold change} < 2.0$ in RT-PCR
 - ++ same algebraic sign and fold change of ≤ -2.0 or fold change ≥ 2.0 in RT-PCR
 - meeting none of the above described criteria
- n. r. = not re-evaluated.

Tab. 5 Accordance of microarray data and RT-PCR analyses 24 h after initiation of adipogenic transdifferentiation – GeneChips HG-U 133A

Gene name (gene symbol)	Identical RNA probes			Additional RNA probes		
	Fold change		Accordance with microarray data	Fold change		Number of accordances with microarray data

tumour necrosis factor receptor superfamily, member 11b (osteoprotegerin) (TNFRSF11B)	-2.9 -29.4	-7.2	++	8.3	-2.4	1

Microarray data and densitometric evaluation of fold changes of gene regulation 24 h after initiation of adipogenic transdifferentiation. The fold changes of gene regulation and the accordance to microarray data are displayed as described for tab. 4. n. a. = not available, mRNA could not be detected in examined probes; n. d./s. = not determined, quantitation was not possible due to absence in transdifferentiated sample; n. d./c. = not determined, quantitation was not possible due to absence in control.

For the microarray analyses performed with the Affymetrix GeneChips HG-U 133 Plus 2.0, a selection of reproducibly regulated genes was re-evaluated by RT-PCR, too. Besides 11 genes with known functions, also 16 at the time point of examination accounted hypothetical gene products were examined. This additional assessment of hypothetical gene products was performed in the course of the medical doctorate of Ulrike Meyer. Even though some of these considered hypothetical gene products have been renamed in the meantime due to novel findings regarding their cellular localisation or structural motifs, their distinct functions are still unknown [GeneCards, 2006].

Both, established and hypothetical genes exhibited distinct regulation for at least one of the both transdifferentiation processes. Most of them showed a reciprocal regulation pattern between both transdifferentiation directions. Additionally, all chosen genes with known functions were listed amongst the top 50 of regulated genes ranked for their potential

relevance during transdifferentiation by bioinformatic analysis (see 4.3.5.2). The RT-PCR experiments were conducted using the same RNA samples as for the second microarray set of adipogenic and osteogenic transdifferentiation. Altogether, microarray data delivered 27 processes of gene regulation for 11 genes with known function and 37 processes of regulation for 16 genes with unknown function. Thereby, each time point of RNA isolation in each transdifferentiation direction was considered as single process. Gel bands for some of the examined genes are depicted in fig. 23. Densitometric analysis of gel bands resulted in confirmation of 23 of the 28 processes of gene regulation, i.e. accordance for 82%, for established genes (tab. 6). Accordance for genes with unknown function was detected in 22 of the 37 processes of gene regulation, i.e. in 59% (tab. 7).

Fig. 23 Examination of gene regulation during adipogenic and osteogenic transdifferentiation by semi-quantitative RT-PCR analyses

Gene expression levels for some of the genes selected for re-evaluation (see also tab. 6) are visualised by gel electrophoresis of RT-PCR products. Eukaryotic translation elongation factor 1 alpha 1 (EF1 α) served as house keeping gene and reported the quality of cDNA. Gene expression is shown for MSCs that were incubated in osteogenic differentiation medium (OM; left side) or adipogenic differentiation medium (AM; right side) for 14 d prior to initiation of transdifferentiation. The change to the respective other differentiation medium induced adipogenic (left side, 3 h AM and 24 h AM) and osteogenic transdifferentiation (right side, 3 h OM and 24 h OM), whereas control samples were further on cultivated in a fresh aliquot of the same differentiation medium as before. Isolation of RNA samples was performed at the stated time points, fully differentiated adipocytes (14 d + 3 h and 14 d + 24 h in AM) and committed osteoblasts (14 d + 3 h and 14 d + 24 h in OM) served as controls.

zinc finger CCCH-type containing 12D (ZC3H12D)	9.69	-5.5	-3.7	OB into AC: 3 h	++
		-1.5	-3.0	OB into AC: 24 h	+
zinc finger CCCH-type containing 12D (ZC3H12D)	9.69	1.9	1.7	AC into OB: 3 h	+
		2.5	3.1	AC into OB: 24 h	++

For hypothetical genes and genes with unknown function, the bioinformatic score (see 4.3.5.2) and fold changes of gene expression obtained by microarray data as well as densitometric evaluation are displayed for adipogenic

and osteogenic transdifferentiation, respectively. Depiction and criteria for evaluation of accordance are the same as stated in tab. 6.

Amongst the established marker mRNAs for adipogenic and osteogenic differentiation, only few of the known adipogenesis-associated genes like LPL, FABP4, and C/EBP α were detected by microarray analyses showing at least 2-fold up-regulation 24 h after initiation of adipogenic transdifferentiation. Densitometric analyses confirmed increased LPL mRNA levels and additionally revealed higher amounts of PPAR γ 2 for cells subjected to adipogenic transdifferentiation. No significant up-regulation was obtained for the osteogenic marker mRNAs shortly after osteogenic transdifferentiation by microarray data as well as by RT-PCR.

4.3.3 Gene ontology analyses

Regulated genes of the single microarray analysis of adipogenic transdifferentiation employing the smaller GeneChips were analysed for their affiliation regarding the main Gene Ontology (GO) categories *cellular component*, *molecular function*, and *biological process* distinguishing between the direction and the time points of regulation.

Using the Affymetrix NetAffx Analysis Center, in the GO class of *molecular function*, many regulated genes belonged to the sub classes of binding and catalytic activity equally for up- and down-regulation and for both time points of RNA isolation (fig. 24). Sub classes included binding, nucleic acid binding or nucleotide binding, and ion binding. For both time points examined, many down-regulated genes belonged to the class of signal transducer activity (fig. 24 C and D). Additionally 24 h after initiation of transdifferentiation, a higher number of regulated genes was affiliated to the category of transporter activity (fig. 24 B). For the GO class of *biological process*, the NetAffx Analysis Center revealed the sub classes of cellular process, physiological process, and regulation of biological process containing high numbers of regulated genes independent from the time point and direction of regulation (fig. 25). In the sub category of cellular process, many genes were further grouped into the sub class of cell communication. Regulated genes belonging to the sub class of physiological process were distributed into the inferior classes of cellular physiological process and metabolism. Furthermore, regulated genes associated with the class of development were found for both regulation directions. More detailed branching into GO classes and the numbers of probe sets contained in each class are stated in the respective GO graphs (fig. 24 and fig. 25).

GOstat analyses for reproducibly regulated genes of the microarray analyses employing the larger GeneChips were performed separately for the different RNA isolation time points. A selection of major over-represented GO classes is displayed separately for both time points and both transdifferentiation directions examined (tab. 8). Complete GOstat results are stated in the appendix (tab. 18, tab. 19, tab. 20, and tab. 21). Major over-represented GO

classes include for both transdifferentiation directions the categories of development, transcription, signal transduction, extracellular region, and cytoskeleton.

Fig. 24 GO graphs of regulated genes associated with the GO classes of molecular function

Regulated probe sets obtained by the first microarray analysis for adipogenic transdifferentiation were submitted into the Affymetrix NetAffx Analysis Center. The results of classification into different and hierarchical structured GO classes are shown separately for numbers of up-regulated genes 3 h (A) and 24 h (B) after initiation of adipogenic transdifferentiation as well as for numbers of down-regulated genes 3 h (C) and 24 h (D) after initiation of transdifferentiation. Thereby, only those GO classes are depicted that contained at least 10 members. Each rectangular node states the designation of the GO class and the corresponding number of included regulated probe sets in parentheses. Moreover, the colour of each node depends on the number of included probe sets ranging from blue boxes with low probe set number to red boxes with high probe set number. Branching into inferior GO categories is indicated by black curves originating from the superior class.

Fig. 25 GO graphs of regulated genes associated with the GO classes of biological process

The distribution of regulated probe sets into the GO classes of *biological process* was obtained and depicted analogously to the GO analysis regarding the class of *molecular function* described for fig. 24. Accordingly, the branching into different and hierarchical structured GO classes is shown separately for numbers of up-regulated genes 3 h (A) and 24 h (B) after initiation of adipogenic transdifferentiation and for numbers of down-regulated genes 3 h (C) and 24 h (D) after initiation of transdifferentiation.

Reliably measured and after initiation of adipogenic transdifferentiation differentially regulated probe sets with at least one P detection call in the compared samples for each experimental set were subjected to Gostat analyses. The total number of regulated and not regulated probe sets detected on the GeneChip served as reference and is given in the respective column. Only over-represented GO classes containing at least 5 genes and a Gostat p-value ≤ 0.1 were considered. The above table shows only a selection of the major over-represented GO classes, complete lists for each time point and transdifferentiation direction are stated in tab. 18 and tab. 19. Adipogenic transdifferentiation exhibited 159 differentially regulated target probe sets that were analysed in reference to all 20,357 reliably measured probe sets for the 3 h time point, 418 target probe sets were referred to 21,892 reliably measured probe sets for the 24 h time point. The GO class of cellular component did not show any relevant over-representation under the stated criteria 3 h after initiation of adipogenic transdifferentiation. Gene symbols are stated according to the HUGO gene nomenclature, those in bold letters rank amongst the top 50 of the bioinformatic scoring depicted in tab. 11.

Reliably measured and after initiation of osteogenic transdifferentiation differentially regulated probe sets with at least one P detection call in the compared samples for each experimental set were subjected to GOstat analyses. The total number of regulated and not regulated probe sets detected on the GeneChip served as reference and is given in the respective column. Only over-represented GO classes containing at least 5 genes and a GOstat p-value ≤ 0.1 were considered. The above table shows only a selection of the major over-represented GO classes, complete lists for each time point and transdifferentiation direction are stated in tab. 20 and tab. 21. Osteogenic transdifferentiation provided 92 target probe sets 3 h after initiation of transdifferentiation that were analysed to the reference of all 22,634 reliably measured probe sets at this time point, for the 24 h time point 1,196 target probe sets were found and analyzed to the reference of all 24,108 reliably measured probe sets. Gene symbols are stated according to the HUGO gene nomenclature, those in bold letters rank amongst the top 50 of the bioinformatic scoring depicted in tab. 11.

4.3.4 Functional grouping of differentially regulated genes

Amongst all reproducibly and at least 2-fold regulated genes that were obtained by employment of the larger GeneChips, members of various signalling pathways were detected (tab. 10). Several genes exhibiting differential regulation shortly after initiation of transdifferentiation were involved in fibroblast growth factor (FGF) signalling, insulin-like growth factor (IGF) signalling, integrin signalling, Wnt/ β -catenin signalling, G-protein signalling, and plasminogen activator urokinase (PLAU) signalling. Moreover, some genes correlated with lipid metabolism, adenosine triphosphate (ATP) metabolism, and adipogenesis. Many of these functionally grouped genes also showed reciprocal regulation patterns regarding the different transdifferentiation directions.

Tab. 10 Regulation of functionally grouped genes

Gene symbol	Gene name	Regulation during	
		adipogenic trans-differentiation	osteogenic trans-differentiation
FGF signalling			
FGF1 ^b	fibroblast growth factor 1	down	up
FGF2	fibroblast growth factor 2	down	-
FGF7	fibroblast growth factor 7	-	up
BCL2	B-cell CLL/lymphoma 2	-	down
IGF signalling			
IGF1 ^b	insulin-like growth factor 1	up	down
IGFBP1 ^b	insulin-like growth factor binding protein 1	-	down
IGFBP5	insulin-like growth factor binding protein 5	up	-
PIK3R3	phosphoinositide-3-kinase, regulatory subunit 3 (p55, gamma)	up	-
YWHAH	tyrosine 3-monooxygenase/tryptophan 5-monooxygenase activation protein, eta polypeptide	-	up
CCND1	cyclin D1	-	up
CCND3	cyclin D3	-	up

integrin signalling			
ITGA3	integrin, alpha 3	-	up
ITGA5	integrin, alpha 5	-	up
VIL2 ^b	villin 2 (ezrin)	down	up
ACTG2	actin, gamma 2, smooth muscle, enteric	down	up
ACTN1	actinin, alpha 1	-	up
ACTC	actin, alpha, cardiac muscle	down	-
CFL2	cofilin 2 (muscle)	down	up
VCL	vinculin	-	up
ILK	integrin-linked kinase	-	up
CDC2	cell division cycle 2, G1 to S and G2 to M	-	up
YWHAH	tyrosine 3-monooxygenase/tryptophan 5-monooxygenase activation protein, eta polypeptide	-	up
IGFBP1 ^b	insulin-like growth factor binding protein 1	-	down
IGFBP5	insulin-like growth factor binding protein 5	up	-
LAMA4	laminin, alpha 4	-	down
Wnt/β-catenin signalling			
WNT5B	wingless-type MMTV integration site family, member 5B	down	up
BIRC5	baculoviral IAP repeat-containing 5	-	up
FOSL1	FOS-like antigen 1	down	-
NRCAM	neuronal cell adhesion molecule	-	down
CCND1	cyclin D1	-	up
ENC1 ^a	ectodermal-neural cortex (with BTB-like domain)	down	-
VEGF	vascular endothelial growth factor	up	down
TLE1	transducin-like enhancer of split 1	-	down
TLE3	transducin-like enhancer of split 3	up	-
ANGPTL4 ^{a, b}	angiopoietin-like 4	-	down
IGF1 ^{a, b}	insulin-like growth factor 1	up	down
SFRP2 ^{a, b}	secreted frizzled-related protein 2	up	down
CYR61 ^{a, b}	cysteine-rich, angiogenic inducer, 61	down	up
COL11A1 ^a	collagen, type XI, alpha 1	-	up
CTGF ^a	connective tissue growth factor	-	up
THBS1 ^a	thrombospondin 1	down	up
TNFRSF11B ^{a, b}	tumor necrosis factor receptor superfamily, member 11b	down	up
WISP1 ^a	WNT1 inducible signalling pathway protein 1	-	up
G-protein signalling			
RGS4 ^b	regulator of G-protein signalling 4	down	up
PLCB4 ^b	phospholipase C, beta 4	down	up
GNB4	guanine nucleotide binding protein (G protein), beta polypeptide 4	down	up
EDG3	endothelial differentiation, sphingolipid G-protein-coupled receptor, 3	up	down
PRKAR2B	protein kinase, cAMP-dependent, regulatory, type II, beta	-	down
NFATC1	nuclear factor of activated T-cells, cytoplasmic, calcineurin-dependent 1	up	-
NFATC4	nuclear factor of activated T-cells, cytoplasmic, calcineurin-dependent 4	up	-
plasminogen activator, urokinase (PLAU) signalling			
PLAUR	plasminogen activator urokinase receptor	-	up
SERPINB2 ^b	serpin peptidase inhibitor, clade B (ovalbumin), member 2	down	-
SERPINE1 ^b	serpin peptidase inhibitor, clade E, member 1	down	up
lipid metabolism			
ACACA	acetyl-Coenzyme A carboxylase alpha	-	down
ACACB	acetyl-Coenzyme A carboxylase beta	up	down
adenosine triphosphate (ATP) metabolism			
PDE4B ^b	phosphodiesterase 4B, cAMP-specific	up	down
ADCY7	adenylate cyclase 7	down	up
adipogenesis-associated genes			
PPARGC1A ^b	peroxisome proliferative activated receptor, gamma, coactivator 1, alpha	up	down
FABP4 ^b	fatty acid binding protein 4, adipocyte	up	-
LPL	lipoprotein lipase	up	-
CEBPA	CCAAT/enhancer binding protein (C/EBP), alpha	up	-

The regulation patterns for both transdifferentiation pathways are depicted for genes grouped into functional classes. A minus indicates that no expression change was detected under the defined criteria (see materials and methods' section), the superscript 'a' marks genes whose transcription is regulated by WNT3A [Jackson et al., 2005; Si et al., 2006], genes ranking amongst the top 50 of the bioinformatic scoring scheme (see next section) are labelled by the superscript 'b'.

4.3.5 Development of a novel bioinformatic scoring scheme for interpretation of microarray results

Due to the high number of at least 2-fold and reproducibly regulated genes during transdifferentiation obtained by employment of the GeneChips HG-U 133 Plus 2.0, a novel empirical scoring system was developed to filter out genes with potential relevance regarding the early events of transdifferentiation.

4.3.5.1 Definition of the criteria for the novel scoring scheme

In collaboration with Prof. Dr. Ralf Zimmer and Dr. Robert Küffner of the Institute of Informatics at the Ludwig Maximilians University in Munich, the criteria defining the bioinformatic scoring scheme were determined and formulas for the calculation of the bioinformatic score were developed and applied to the sum of 8 compared probe pairs.

The design of the bioinformatic score provided high scores for those genes that were significantly regulated and was further elevated if their regulation was reciprocal regarding the two transdifferentiation pathways. Moreover, the scoring scheme assessed the reproducibility of regulation events in repeated experiments, thus evaluating datasets from different biological samples obtained by different microarray sets. Only those probe sets attributed with an increase or decrease call by the Affymetrix comparison algorithm were taken into account. The signal log ratios obtained from corresponding pairs (signal of transdifferentiated sample versus signal of differentiated control sample) determined the extent of regulation. Furthermore, to incorporate the reliability of the signal intensities, log change p-values were factored in to weight the log changes. The weighted fold changes displayed a unimodal, almost symmetrical distribution. Given the intensity distribution of the individual microarray sets, z-scores of the weighted fold changes were used to empirically quantify the strength of regulation.

The $score_S$ calculated the extent of reciprocal regulation for probe set s from RNA sample r .

$$score_S(s, r) = \left| z_{3h}^{AC:OB}(s, r) - z_{3h}^{OB:AC}(s, r) \right| + \left| z_{24h}^{AC:OB}(s, r) - z_{24h}^{OB:AC}(s, r) \right| + \left| z_{24h-3h}^{AC:OB}(s, r) - z_{24h-3h}^{OB:AC}(s, r) \right|$$

with $AC:OB$ = osteogenic transdifferentiation, $OB:AC$ = adipogenic transdifferentiation.

Thereby, the combination of z-scores of the respective time points in the first and second summand selected for probe sets with high fold changes and preferably reciprocal regulation

between different transdifferentiation directions. The third summand quantified the reciprocal regulation of weighted log fold changes for the 3 h and 24 h time points of the same transdifferentiation direction.

If several probe set representing the same gene were combined to a set of probe sets $g_{s,r}$ that measures gene g in sample r . Accordingly, the single gene score for each microarray set, i.e. for the different biological samples, was calculated by:

$$score_G(g, r) = \frac{1}{\sqrt{|g_{s,r}|}} \sum_{s \in g_{s,r}} score_S(s, r)$$

All single gene scores derived from single RNA samples $r \in R$ were averaged over the set of samples R . An uncentred correlation coefficient was employed to weight this average, which resulted in higher scores if time courses in R were reproducible. Thus, genes were ranked by their relevance via:

$$score_{G,R}(g) = ucorr(Z(r_1), Z(r_2)) \cdot \frac{1}{|R|} \sum_{r \in R} score_G(g, r), \text{ with}$$

$$Z(r) = \begin{matrix} ++ \\ s \in g_{s,r} \end{matrix} < z_{3h}^{AC:OB}(s, r) - z_{3h}^{OB:AC}(s, r), z_{24h}^{AC:OB}(s, r) - z_{24h}^{OB:AC}(s, r), z_{24h-3h}^{AC:OB}(s, r) - z_{24h-3h}^{OB:AC}(s, r) >$$

Thereby, the single gene scores, i.e. $score_G(g, r)$ (named score 1 and score 2 in tab. 11), rank a gene g based on the first and the second measured sample r corresponding to the different biological samples. The combined score, i.e. $score_{G,R}(g)$, quantifies the total relevance of the gene and was used to rank the genes in descending order.

4.3.5.2 Ranking of differentially regulated gene products by the novel scoring scheme

The 50 highest-ranking genes are listed in tab. 11 according to their descending bioinformatic score with additional information regarding the regulation patterns detected by microarray analyses and their functional properties. The signal log changes of the 8 highest-ranking genes are plotted in fig. 26. These graphs are representative for many of the highly ranked genes as they exhibit reciprocal regulation between the different transdifferentiation pathways in at least one of the time points examined. Regarding their functional properties, many of the highly ranked genes were associated with signalling pathways, morphology, cell differentiation, lipid metabolism, cellular biosynthesis, and transcription. Moreover, amongst the top 50-ranking genes more than 60% were also detected by Gostat analyses as members of over-represented GO categories (tab. 16, tab. 17, tab. 18, and tab. 19).

Tab. 11 Top 50 of regulated genes ranked by their bioinformatic scoring

#	Regulation in		Com- bined score	Corre- lation	Score 1	Score 2	# of probe sets	Gene symbol	Gene name	Functions
	adipo- genic transdiff.	osteo- genic transdiff.

Regulated genes are listed by their descending combined score that quantifies the total relevance of each gene resulting from the correlation of both single gene scores 1 and 2. The number of regulated probe sets that were taken into account for the same gene is stated in the respective column. Additionally, up- or down-regulation of genes in osteogenic and adipogenic transdifferentiation, respectively, is displayed according to the microarray data. Thereby, -- indicates absence of any decrease or increase call, less than 2-fold regulations are stated in parentheses, and the asterisk indicates that this gene only exhibited reciprocal regulation 24 h after initiation of transdifferentiation, whereas the 3 h time point showed no regulation in osteogenic but up-regulation in adipogenic transdifferentiation.

a = signal transduction, b = morphology, c = cell differentiation, d = lipid metabolism, e = cellular biosynthesis, f = transcription, g = G-protein signalling, h = FGF signalling, i = IGF signalling, j = integrin signalling, k = osteoclastogenesis, l = inhibition of apoptosis, m = PLAU signalling, n = ATP metabolism, o = adipogenesis.

Fig. 26 Plot of gene regulation patterns of the 8 most highly ranked genes

Signal \log_2 ratios obtained by two microarray experiments (exp 1 and 2) represent changes of gene expression 3 h and 24 h after initiation of transdifferentiation, respectively. Transdifferentiation from adipocytes into osteoblasts is stated by continuous curves, whereas transdifferentiation of pre-osteoblasts into adipocytes is shown by dotted curves. Multiple curves for the same gene in a single transdifferentiation direction show regulation of multiple probe sets for the corresponding gene. Expression levels of transdifferentiated samples were compared to control mRNA levels of differentiated cells. Accordingly, the increase of gene expression is stated by positive values while the decrease of gene expression is given by negative values.

4.4 Functional testing of human recombinant proteins during differentiation and transdifferentiation

Amongst the established genes, several genes that had received high ranking by bioinformatic evaluation (see 4.3.5.2) encode for secreted proteins. Prior to functional testing of some of the respective gene products in our cell culture system that were commercially available and produced in our own laboratory, respectively, the regulation patterns of gene expression were evaluated by semi-quantitative RT-PCR (see 4.3.2).

For TNFRSF11B, SFRP2, FGF1, CYR61, and IGF1, reciprocal regulation patterns of gene expression during the different transdifferentiation pathways were detected by microarray analyses and confirmed by semi-quantitative RT-PCR analyses (except for the change of SFRP2 during osteogenic transdifferentiation). While TNFRSF11B and CYR61 declined during adipogenic transdifferentiation and augmented during osteogenic transdifferentiation, SFRP2 and IGF1 showed the reciprocal regulation pattern with decreasing mRNA amounts for osteogenic but increasing mRNA levels for adipogenic transdifferentiation.

Since distinct changes of gene expression during the early events of transdifferentiation should also influence the feasibility of differentiation of MSCs, at first normal adipogenic and osteogenic differentiation were examined in presence of the recombinant proteins encoded by these genes.

4.4.1 Secreted proteins tested in differentiation of MSCs without effect

According to the changes of TNFRSF11B and CYR61 mRNA levels shortly after initiation of both transdifferentiation pathways, the corresponding proteins rhTNFRSF11B and rhCYR61 were supposed to decrease adipogenic but to enhance osteogenic differentiation. In contrast, due to the changes of SFRP2 and IGF1 mRNA levels rmSFRP2 and rhIGF1 were expected to increase adipogenic but to reduce osteogenic differentiation.

Differentiation was monitored by staining of lipid vesicle accumulation for adipogenic differentiation whereas osteogenic differentiation was assessed by staining of ALP activity and mineralised extracellular matrix in the cell monolayers. Control samples incubated in the respective differentiation medium without recombinant proteins and with additional protein solvent (0.0005% BSA in PBS), respectively, showed normal adipogenic and osteogenic differentiation of MSCs. Employment of the above-mentioned recombinant proteins in parallel with the respective differentiation factors did not cause noticeable alteration of differentiation in our cell culture system. As an exception, for addition of rmSFRP2 to osteogenic differentiation medium cells were observed to detach within the first days of incubation. For adipogenic differentiation, the application of these recombinant proteins prior to and during incubation with the differentiation factors was tested but yielded no effect either. Moreover, rmSFRP2 was not able to induce adipogenic differentiation in the absence of the

conventional adipogenic differentiation factors. Similarly, TNFRSF11B could not provoke osteogenic differentiation in absence of the conventional osteogenic differentiation supplements.

4.4.2 Effect of FGF1 on adipogenic differentiation and transdifferentiation

Distinct changes in mRNA levels for FGF1 early after initiation of transdifferentiation obtained by microarray data and RT-PCR analysis indicated an inhibitory effect of FGF1 protein on adipogenic and an enhancing effect on osteogenic development. At first, the influence of rhFGF1 on adipogenic and osteogenic differentiation was examined.

Addition of 6 - 50 ng/ml rhFGF1 during adipogenic differentiation resulted in significant decrease of adipocyte-specific lipid vesicle accumulation (fig. 27 and fig. 28). This finding was irrespective of the prior incubation of confluent MSCs with sole 6 - 50 ng/ml rhFGF1 followed by simultaneous application of FGF1 and adipogenic supplements. Since gaps in the cell monolayers appeared occasionally after 14 d of incubation during application of 50 ng/ml FGF1 with adipogenic supplements, the semi-quantitative assessment of lipid vesicle accumulation was only performed for the lower concentrations of rhFGF1. Thereby, rhFGF1 had no proliferative effect neither on subconfluent nor on confluent MSCs (fig. 29). Sole pre-incubation with 6 - 50 ng/ml rhFGF1 previous to exposure to adipogenic medium without any rhFGF1 could not inhibit accumulation of lipid vesicles. According to the observed effects of rhFGF1 on adipogenic differentiation, adipogenic transdifferentiation was also clearly diminished by simultaneous addition of 6 - 50 ng/ml rhFGF1 (fig. 30).

Application of 50 ng/ml rhFGF1 in parallel with osteogenic supplements demonstrated no alterations of osteogenic differentiation, neither in the temporal course nor in the amount of ALP activity and mineralisation of extracellular matrix. Incubation with 50 ng/ml rhFGF1 alone, i.e. without osteogenic supplements could not provoke osteogenic differentiation of confluent MSCs either.

Application of heparin alone that is commonly used to enhance the biological activity of FGF1 [Burgess et al., 1994; Wesche et al., 2005] displayed no influence on the conducted experiments.

Attempts to detect FGF1 protein in preparations of intracellular and supernatant protein by Western blotting failed while controls of as little as 25 ng rhFGF1 produced strong bands.

Fig. 27 Effect of different concentrations of rhFGF1 on adipogenic differentiation

Representative results are depicted for lipid vesicle accumulation that was visualised for normal adipogenic differentiation of MSCs (A - D) and for incubation in AM supplemented with 20 U/ml heparin alone (E - G) or with 20 U/ml heparin plus different concentrations of FGF1 as stated on the left side (H - P). Thereby, intracellular lipid vesicles were stained by Oilred O and cell nuclei were counterstained with hemalaun as indicated at the beginning of the experiment (0 d) and after 7 d, 14 d, and 21 d of incubation in the respective medium. The accumulation of red lipid vesicles during exposure to adipogenic differentiation medium (B - D) and during incubation in adipogenic differentiation medium supplemented with heparin alone (E - G) showed distinct adipogenic differentiation. Incubation with various concentrations of rhFGF1 strongly reduced lipid vesicle accumulation (H - P). Scale bar = 100 μ m.

Fig. 28 Semi-quantitative evaluation of lipid vesicle accumulation during adipogenic incubation and FGF1 treatment

After 7 d and 14 d of incubation in adipogenic medium with or without heparin and FGF1 as indicated, lipid vesicle-containing area was determined. Mean \pm SEM of 3 (7 d) and 4 (14 d) independent experiments with 6 fields analysed per experiment and incubation condition are displayed. The asterisks mark $P < 0.05$ compared to the adipogenic control (0 ng/ml FGF1, without heparin) as well as to the heparin control (0 ng/ml FGF1, with heparin).

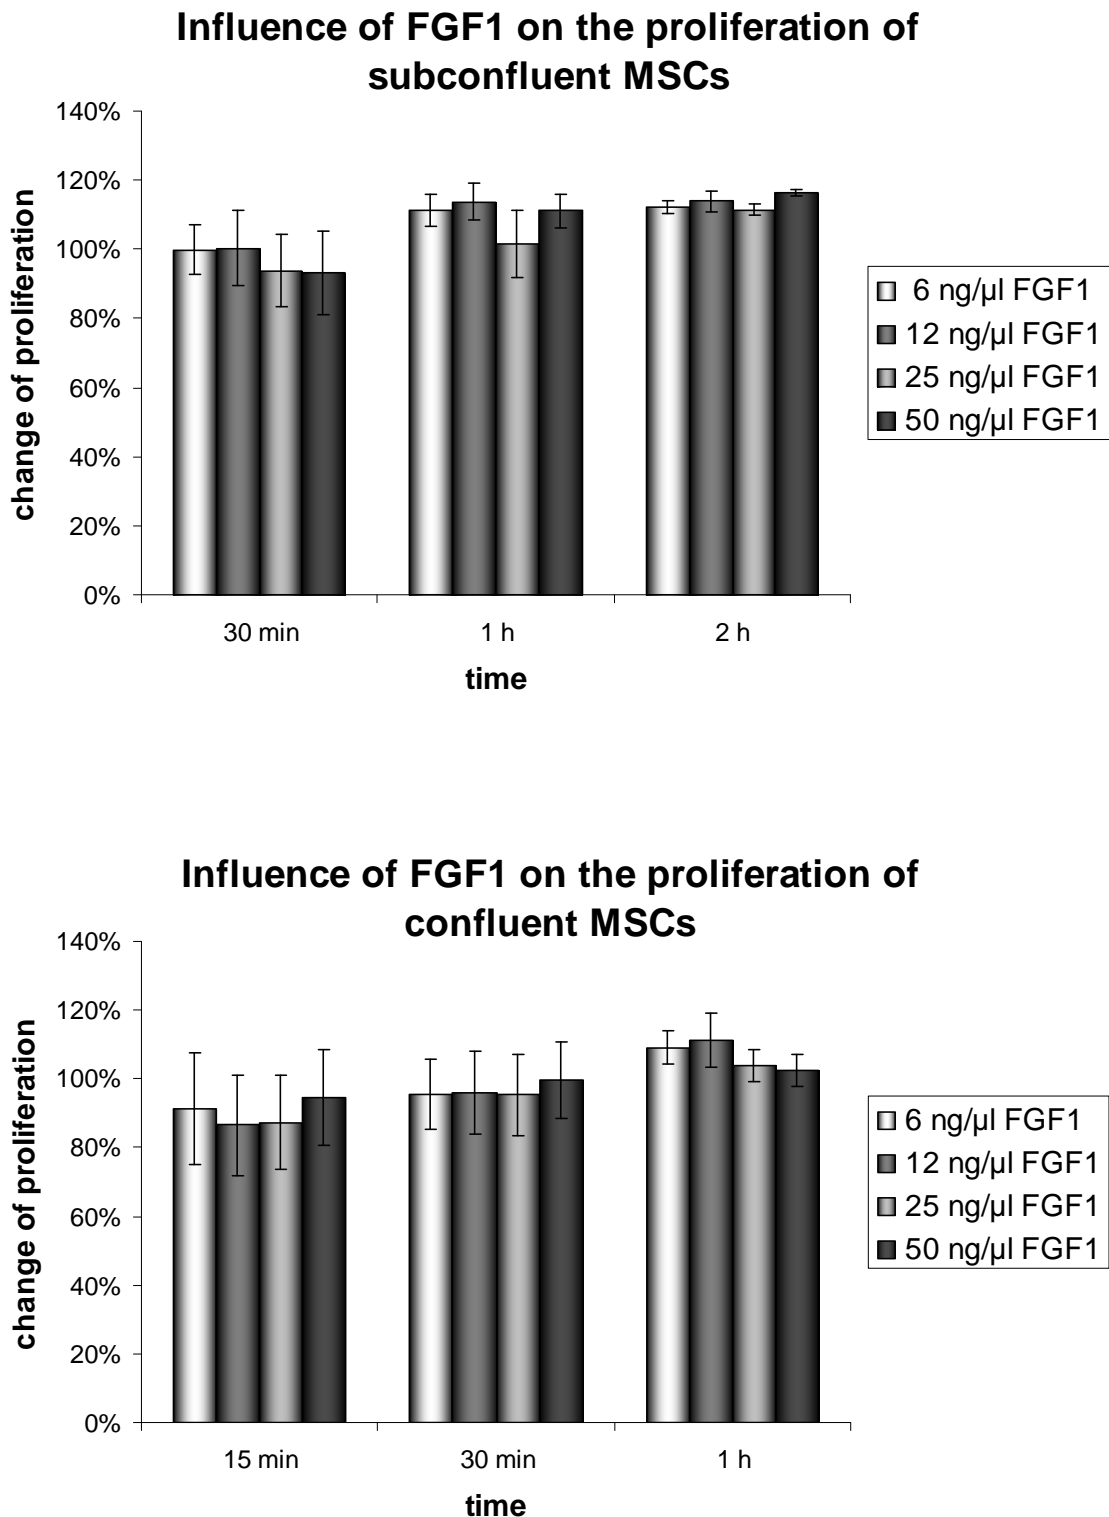

Fig. 29 Influence of rhFGF1 on proliferation of MSCs

Different concentrations of rhFGF1 were examined for their potential proliferative effect on subconfluent ($n = 3$; upper graph) and confluent MSCs ($n = 4$; lower graph). Proliferation was normalised on proliferation of MSCs incubated in control medium without rhFGF1 for the same time period as indicated. Change of proliferation is given as mean + SEM. Addition of rhFGF1 did not change the proliferation rate of MSCs neither for the subconfluent nor for the confluent assay.

Fig. 30 Influence of rhFGF1 during adipogenic transdifferentiation

Representative staining of osteogenic and adipogenic markers is shown for undifferentiated cells as well as for (trans)differentiated cells in presence or absence of FGF1. As controls, MSC monolayers were subjected to normal osteogenic (C = 14 d and D = 28 d) and adipogenic differentiation (F = 14 d) as well as normal adipogenic transdifferentiation (G = 14 d in osteogenic medium + 14 d in adipogenic medium) and adipogenic transdifferentiation in presence of heparin (H = 14 d in osteogenic medium + 14 d in adipogenic medium plus 20 U/ml heparin). Moreover, the effect of different concentrations of rhFGF1 (I = 6 ng/ml, J = 12 ng/ml, K = 25 ng/ml, L = 50 ng/ml) on adipogenic transdifferentiation (14 d in osteogenic medium + 14 d in adipogenic medium plus 20 U/ml heparin and rhFGF1) was assessed.

Alizarin red S staining was performed at day 0 (A phase contrast image, B bright field image) and for controls incubated in normal osteogenic differentiation medium (C and D) to visualise calcium deposition in the extracellular matrix. Pre-osteoblasts, obtained after 14 d of osteogenic differentiation were used to start transdifferentiation experiments (C) To detect lipid vesicle accumulation, Oilred O staining was carried out at day 0 (E) as well as at the end points of incubation for all controls and samples exposed to adipogenic differentiation and transdifferentiation assays (I - L) as stated above. While adipogenic differentiation (F) and transdifferentiation (G) yielded high lipid vesicle accumulation, adipogenic reprogramming was strongly decreased in presence of rhFGF1 (I - L). Application of heparin alone did not alter adipogenic transdifferentiation (H). Scale bar = 100 μ m.

5 Discussion

The bone marrow and other sites comprise multipotent MSCs that give rise to a variety of mesenchymal lineages as adipocytes and osteoblasts [Barry and Murphy, 2004; Caplan, 1991; Muraglia et al., 2000; Nöth et al., 2002a; Pittenger et al., 1999; Prockop, 1997]. Thereby, osteoblasts play a crucial role for bone remodelling and fracture healing [Krane, 2005; Martin and Sims, 2005]. Since with ageing, an inverse relationship between bone and adipose tissue generation was reported [Beresford et al., 1992; Burkhardt et al., 1987; Gimble et al., 2006; Koo et al., 1998], lack of osteogenic differentiation of MSCs as well as transdifferentiation (reprogramming) of osteoblasts into adipocytes could contribute to this degeneration process. Therefore in the work presented here, bone-marrow derived human MSCs were not only proven to be able to differentiate into adipocytes and osteoblasts as described previously [Schütze et al., 2005b] but also plasticity between the osteogenic and adipogenic lineage was detected and further examined in our cell culture system.

5.1 MSCs are capable of adipogenic and osteogenic differentiation and transdifferentiation

Primary MSCs used in our cell culture system were proven to differentiate into adipocytes and osteoblasts, respectively, by incubation in the established differentiation media [Jaiswal et al., 1997; Pittenger et al., 1999]. Moreover, adipocytes and pre-osteoblasts derived from these MSCs were still capable of reprogramming into the respective other lineage simply by application of the respective other differentiation medium. Thereby, differentiation as well as transdifferentiation was accompanied by the expression of the respective lineage-specific marker genes, thus proving the attainment of the adipogenic or osteogenic phenotype.

Conventional osteogenic differentiation was characterised by increasing expression levels of the osteoblast-specific marker mRNAs for ALP and OC as well as by ALP activity and deposition of mineralised matrix in the monolayers (fig. 10, fig. 11, and fig. 12) [Aubin, 1998; Stein et al., 1996]. After 28 d of osteogenic incubation, also weak expression of adipogenic marker mRNAs (PPAR γ 2 and LPL) was detected. On the one hand, this observation could arise from some pre-osteoblasts that underwent spontaneous transdifferentiation into adipocytes. Hence together with other events, this could also partly account for the age- and disease-related gain of adipose tissue in human bone marrow [Beresford et al., 1992; Koo et al., 1998]. On the other hand, further microarray analyses performed by our group detected low expression levels of PPAR γ 2 even in undifferentiated MSCs (personal communication with Prof. Dr. F. Jakob). This suggests that expression of PPAR γ 2 alone is not sufficient to report the adipogenic phenotype but the inductive factors of the adipogenic differentiation medium aid to its adipogenic effect. Moreover, weak expression of PPAR γ 2 during

osteogenic induction was also reported by Song and Tuan [2004] but did not result in adipocyte-specific lipid vesicle accumulation.

Thus, considering the mRNA levels of osteogenic and adipogenic markers during osteogenic differentiation we employed pre-osteoblasts after up to 15 d of osteogenic incubation for adipogenic transdifferentiation experiments. These pre-osteoblasts expressed OC and from day 10 onwards also ALP while no adipogenic markers were detected during this time frame. Moreover after 14 d of osteogenic incubation, calcium hydrogen phosphate deposition commenced and homogeneous staining for ALP activity all over the monolayer was observed indicating uniform differentiation into pre-osteoblasts. Transdifferentiation of these pre-osteoblast into differentiated adipocytes was obtained after 14 d of incubation in adipogenic differentiation medium with strong expression of the adipogenic mRNA markers (PPAR γ 2 and LPL) while the osteogenic ones decreased (ALP) and disappeared (OC), respectively (fig. 10). The loss of osteogenic marker expression after adipogenic transdifferentiation and the above mentioned ALP activity stretching homogeneously over the monolayer excluded significant contribution of possibly undifferentiated MSCs to the resulting adipocytes. Furthermore, transdifferentiated adipocytes even displayed larger areas of lipid vesicle accumulation than conventionally differentiated ones derived from undifferentiated MSCs (fig. 17). Again, this supports the hypothesis of spontaneous adipogenic conversion of pre-osteoblasts that is further enhanced by the adipogenic factors of the medium.

Conventional adipogenic differentiation for 14 d yielded adipocytes strongly expressing adipocyte-specific marker mRNAs (PPAR γ 2 and LPL) and containing intracellular lipid vesicles (fig. 10 and fig. 13) [Pittenger et al., 1999; Rosen et al., 2000]. Hence, osteogenic transdifferentiation was induced in these fully differentiated adipocytes and resulted in the conversion towards osteoblasts after 4 weeks of subsequent incubation in osteogenic differentiation medium (fig. 17 and fig. 18). Transdifferentiated osteoblasts displayed strong expression of osteogenic marker mRNAs (ALP and OC) and mineralisation of their extracellular matrix. However, adipogenic marker mRNA levels (PPAR γ 2 and LPL) persisted and the monolayers still contained residual lipid vesicles. These findings indicate that the osteogenic transdifferentiation pathway is less efficient than the adipogenic one.

Although the cells employed in our system are derived from a heterogeneous population of MSCs, i.e. not from single cell clones, the sole contribution of possibly undifferentiated MSCs to the formation of the osteogenic phenotype seems unlikely, since adipogenic markers are strongly expressed and the accumulation of at least small lipid vesicles can be observed for the majority of the cells prior to induction of osteogenic transdifferentiation. Moreover in contrast to the adipogenic differentiation medium, the composition of the osteogenic differentiation medium does not differ much from that of the propagation medium also containing one of the osteoinductive components (L-ascorbic acid 2-phosphate) [Jaiswal et

al., 1997; Nöth et al., 2002a]. Thus, while conventional osteogenic differentiation starting from undifferentiated MSCs can be achieved easily [Jaiswal et al., 1997; Nöth et al., 2002a; Schütze et al., 2005b], the factors included in osteogenic differentiation medium might not be sufficient to induce osteogenic transdifferentiation in all cells of the monolayer. Especially considering activation of the complex Wnt signalling pathway which is mandatory for conventional osteogenic differentiation [Gregory et al., 2005; Rawadi et al., 2003] also as a prerequisite for osteogenic transdifferentiation of adipocytes, the osteogenic factors applied with the differentiation medium may not be specific enough in the latter process.

Even though the existence of transdifferentiation *in vivo* has not been proven yet and some work regards changes in lineage phenotype as a consequence of cell fusion or heterogeneity [Orkin and Zon, 2002; Terada et al., 2002; Verfaillie, 2002; Ying et al., 2002] our findings are in accordance with the results of *in vitro* experiments showing plasticity of adipocytes [Park et al., 1999] and osteoblasts [Nuttall et al., 1998; Schiller et al., 2001]. Moreover, transdifferentiation at the single cell level was reported *in vitro* for human MSC-derived osteoblasts, adipocytes, and chondrocytes [Song and Tuan, 2004]. Regarding the progression of transdifferentiation, de-differentiation prior to re-differentiation and a direct change between lineage phenotypes have been considered as possible mechanisms [Song and Tuan, 2004; Verfaillie, 2002].

Regarding the whole organism, fatty degeneration was described to arise with or without relation to age. Independent of age, the muscle tissue of the shoulder's rotator cuff was shown to develop adipogenic conversion after trauma [Goutallier et al., 1994; Moore and Dawson, 1990]. More commonly, age-related increase of adipose tissue in the bone marrow was observed as soon as in the first decade of life in the diaphysis of long bones [Nakagaki et al., 1996; Zawin and Jaramillo, 1993] and more strikingly in older age. The associated simultaneous loss of bone mass is considered to contribute to age-related diseases like osteopenia and osteoporosis [Burkhardt et al., 1987; Gimble et al., 2006; Justesen et al., 2001; Koo et al., 1998; Meunier et al., 1971; Pei and Tontonoz, 2004; Rosen and Bouxsein, 2006]. Therefore, the reprogramming of pre-osteoblasts into adipocytes shown in our *in vitro* experiments could also take place *in vivo* and enhance the above mentioned age- and disease-related changes.

Knowledge about the molecular events initiating adipogenic and osteogenic transdifferentiation, respectively, that are unknown so far could help to understand the mechanisms contributing to the fatty degeneration of bone marrow and provide means to counteract this phenomenon. Thus after establishment of our *in vitro* system allowing for transdifferentiation between the adipogenic and osteogenic lineage, we performed Affymetrix microarray analyses to detect changes in gene expression shortly after initiation transdifferentiation.

5.2 Microarray analyses revealed reproducible regulation of a high number of gene products during transdifferentiation

Affymetrix microarray analyses allowed for detection of gene expression patterns shortly after initiation of transdifferentiation comparing mRNA levels of transdifferentiated cells with those of cells further on incubated in the same differentiation medium as before. Thereby, the employment of a single MSC batch together with the smaller GeneChips HG-U 133A that were able to detect differential regulation of 14,500 genes served for the obtainment of a first insight into gene expression changes during adipogenic transdifferentiation and for determination of the reliability of the microarray data regarding our cell culture system. Re-evaluation of microarray data by semi-quantitative RT-PCR for highly regulated genes yielded 91% accordance for identical RNA samples and 45% accordance for both of two additional RNA preparations of further MSC batches (tab. 4 and tab. 5). Moreover, the confirmation of up-regulation for adipocyte-specific gene products (APM1 and FABP4) during adipogenic transdifferentiation met the expectations. These findings stated the general reliability and significance of the Affymetrix microarray data for our cell culture system, but also demonstrated some variations obviously dependent on the different MSC batches.

The more complete Affymetrix GeneChips HG-U 133 Plus 2.0 that represent an extended version of the GeneChips HG-U 133A offered the ability to determine regulation of 38,500 genes considered to represent the whole human genome. As these GeneChips became available, different batches of MSCs were employed to conduct two microarray analyses per transdifferentiation direction, which allowed for detection of reproducibly regulated mRNA species. Thereby, the re-evaluation of changes in mRNA levels 3 h and 24 h after initiation of transdifferentiation for selected genes again confirmed the reliability and significance of microarray data regarding our cell culture system. Regulation of established genes showed high accordance, i.e. in 82% of the examined regulation events (fig. 23 and tab. 6). Since transdifferentiation processes may involve novel genes whose functions are not known so far, additional assessment of at the time point of examination hypothetical gene products was performed for 16 genes in the course of the medical doctorate of Ulrike Meyer. Here, the re-evaluation of regulation patterns yielded slightly less accordance (59%) (tab. 7). This lower consistence could be correlated with uncertainties regarding the respective mRNA sequences of hypothetical genes possibly leading to cross hybridisation on the GeneChips or sub-optimal detection by RT-PCR.

Furthermore, only about 60% of the genes found to be regulated by the first single array analysis for adipogenic transdifferentiation showed reproducible regulation patterns in the subsequent microarray analyses for the same transdifferentiation direction. Due to the higher accordance between microarray data and RT-PCR experiments, this variability seems to originate from differences in MSC batches as observed by examination of additional RNA

samples for re-evaluation of the first microarray analysis. Nevertheless, the larger GeneChips detected reproducible regulation of a high number of genes, amongst them many that could not be assessed by the smaller GeneChips. Many of the reproducibly regulated genes found by usage of the larger GeneChips showed reciprocal regulation patterns regarding the different transdifferentiation directions. Furthermore, osteogenic reprogramming was characterised by increases in gene expression for the majority of regulated genes whereas adipogenic transdifferentiation was accompanied by decreased mRNA levels for the majority of regulated genes. The active induction of gene expression during the osteogenic switch suggests the requirement for active repression of the adipogenic pathway. Concordantly, the activation of nuclear NAD-dependent protein deacetylase sirtuin 1 was reported to decline adipogenic conversion of murine MSCs during osteogenic incubation *in vitro* [Bäckesjö et al., 2006]. Hence, impairment of active repression of the adipogenic pathway in MSCs or pre-osteoblasts could clear the way for adipogenic development and therefore contribute to the adipogenic degeneration of the bone marrow mentioned before.

Since Song et al. [2006] assumed that transdifferentiation of differentiated phenotypes occurs via dedifferentiation into a stem cell like state followed by redifferentiation into another phenotype, they performed microarray analyses that compared differentiated cells (osteoblasts, adipocytes, and chondrocytes) with undifferentiated MSCs and dedifferentiated cells of each lineage, respectively. Whereas in this experimental setting the three groups differed in duration of their cultivation, incubation periods between compared samples were identical in our experiments thus avoiding any possible influence of *in vitro* ageing of the cells on changes in gene expression [Baxter et al., 2004; Bonab et al., 2006; Serakinci et al., 2004]. Regardless of this consideration, some genes were regulated in both studies (e.g. BIRC3, IGFBP5, IGF1, LAMA4, PRKAR2B, RGS2, RGS4, SERPINE1, TNFRSF11B, and YWHAH). This finding might suggest the occurrence of some dedifferentiation events in our cell culture system of transdifferentiation. However, gene regulation patterns between the adipogenic and osteogenic transdifferentiation direction were often reciprocal regarding our cell culture system, which therefore favours the assumption of immediate induction of transdifferentiation.

Further analyses grouped regulated gene products into GO classes according to their association with *cellular components*, *molecular functions*, and *biological processes*. Regarding the single microarray analysis for adipogenic transdifferentiation, regulated genes were affiliated into the subclasses of *molecular function* and *biological process* resulting in separate GO graphs distinguishing between the time point of gene regulation (3 h and 24 h after initiation of adipogenic transdifferentiation, respectively) as well as between up- and down-regulation of mRNA amounts (fig. 24 and fig. 25). Up-regulation of the majority of

genes associated with transcription and signal transduction 3 h after initiation of transdifferentiation indicated the requirement for *de novo* synthesis of gene products and subsequent activation of signalling pathways. The sustainment of regulated genes in the subclass of signal transduction 24 h after initiation of transdifferentiation supported this assumption. Moreover, changes in secretion of proteins at this time point were assumed to occur due to regulation of extracellular region-associated genes while up-regulation of catalytic transporter activity- as well as lipid metabolism-correlated genes pointed at the onset of an adipogenesis-related metabolism. GOstat analyses of reproducibly regulated gene products obtained by usage of the larger GeneChips also resulted in over-representation of genes correlated with signal transduction not only for both time points examined but also for the different transdifferentiation directions (tab. 8 and tab. 9). In accordance with the data for the single microarray analysis mentioned above, transcription-associated genes were only enriched 3 h after initiation of adipogenic transdifferentiation. Moreover, almost all GO classes that showed over-representation for the first microarray analysis were obtained as well after the GO analyses for reproducibly regulated genes. After 24 h, reproducibly regulated genes mainly accumulated in the groups of development, extracellular region, morphogenesis, and cytoskeleton for both transdifferentiation directions. Furthermore, osteogenic transdifferentiation was accompanied by over-representation of genes affiliated to the categories of cell cycle and chromosome. Altogether, these data suggest that transdifferentiation requires alteration of signalling pathways and development-associated gene products. Moreover, adipogenic transdifferentiation begins with early regulation of transcription while genes regarding morphological changes are important for both transdifferentiation directions 24 h after initiation of the reprogramming.

Only a few of the known mRNA markers of adipogenesis were up-regulated during adipogenic transdifferentiation (tab. 10) but none of the osteogenic ones showed differential regulation in neither of the transdifferentiation pathways within the time frame of 24 h after initiation of transdifferentiation. Hence, other genes that have not been related to adipogenesis and osteogenesis or whose functions are unknown so far are likely to be involved in the onset of transdifferentiation events especially regarding the osteogenic switch of adipocytes. Therefore, the development of a novel bioinformatic scoring scheme helped to filter out gene products with possibly high relevance for initiation of transdifferentiation.

5.3 The development of a novel bioinformatic scoring scheme improves the detection of gene products potentially important for transdifferentiation

The examination of genome-wide gene expression patterns shortly after initiation of adipogenic and osteogenic transdifferentiation by microarray analyses yielded high numbers of reproducibly regulated genes (fig. 22). Therefore, transdifferentiation seemed to comprise complex mechanisms to abrogate the current lineage phenotype and to switch to the

respective other one involving far more and other genes than described for conventional differentiation.

Our empirical scoring scheme provided a means to prioritise gene products for further analyses due to the reproducibility, extent, and reciprocity of their regulation regarding the adipogenic and osteogenic transdifferentiation direction. Ranking of genes according to their score listed factors with possibly highest relevance for transdifferentiation. Thereby, genes with reciprocal regulation patterns between the reverse transdifferentiation pathways were considered very important and awarded high scores because they might be involved in balancing and controlling adipogenic and osteogenic lineage development. Moreover, a reciprocal correlation between the expression of lineage-specific genes during normal differentiation starting from stem cells was reported to partly inhibit the differentiation into the respective other lineage [Akune et al., 2004; Nuttall and Gimble, 2004]. The value of the bioinformatic score was further confirmed by affiliation of many of the top 50-ranking genes to over-represented GO categories re-emphasising their relevance (tab. 11). Thus, this assessment of the relevance of regulated genes set the stage for further functional evaluation and analysis of several highly ranked genes.

5.3.1 Members of several signalling pathways are highly regulated during transdifferentiation

Together with further at least 2-fold regulated genes, several of the top 50-ranking ones were associated with signalling pathways (tab. 10). Amongst them integrin, IGF, Wnt/ β -catenin, G-protein, and FGF signalling comprised the highest numbers of members.

Most of the genes associated with integrin signalling showed up-regulation during osteogenic transdifferentiation which pointed towards changes of the actin cytoskeleton that is organised by integrins [Giancotti and Ruoslahti, 1999]. Both, VIL2 and IGFBP1 are ranking amongst the top 50 of the bioinformatic scoring. Thereby, VIL2 is acting as a membrane-cytoskeletal linking protein that governs cell-cell and cell-matrix adhesions [Berryman et al., 1993; Hiscox and Jiang, 1999] and IGFBP1 is recognised by the $\alpha 5\beta 1$ integrin receptor and influences phosphorylation of focal adhesion kinase [Ricort, 2004]. Furthermore, also members of PLAU signalling that has been described to affect integrin signalling and matrix remodelling were differentially regulated [Choong and Nadesapillai, 2003].

Regarding IGF signalling, augmentation of IGF1 mRNA levels shortly after initiation of adipogenic transdifferentiation suggested promotion of the adipogenic lineage as reported for murine and human pre-adipocytes [Boney et al., 1994; Schmidt et al., 1990]. Thereby, besides paracrine signalling also an autocrine function of IGF1 and IGFbps was assumed that was likely to affect transdifferentiation in our cell culture system [Wabitsch et al., 2000]. IGF1 has also been connected to Wnt signalling since its expression was induced by WNT1 in 3T3-L1 preadipocytes where presence of IGF1 prevented these cells from apoptosis after

serum withdrawal [Gagnon et al., 2001; Longo et al., 2002]. However, since WNT1 gene expression was not altered during the transdifferentiation experiments and only serum-containing incubation conditions were applied, the action of IGF1 as component of Wnt signalling seemed unlikely for reprogramming. Contrary to our expectations, external application of rhIGF1 had no influence on adipogenic and osteogenic differentiation in our cell culture system, but could nevertheless influence transdifferentiation events, which remains to be elucidated.

Also several other gene products correlated with Wnt/ β -catenin signalling showed up- or down-regulation during the transdifferentiation processes. For conventional differentiation, activation of this signalling pathway enhances osteogenesis while adipogenesis is prevented [Bennett et al., 2002; MacDougald and Mandrup, 2002; Rawadi et al., 2003; Ross et al., 2000]. High relevance amongst the factors of Wnt/ β -catenin signalling was attributed to TNFRSF11B (= OPG), SFRP2, and CYR61 by our bioinformatic scoring.

Application of rhTNFRSF11B in our *in vitro* cell culture system however neither changed adipogenic and osteogenic differentiation nor induced spontaneous osteogenesis in undifferentiated MSCs. Nevertheless, since TNFRSF11B also inhibits the development of osteoclasts [Lacey et al., 1998; Simonet et al., 1997] its function may rather affect the *in vivo* situation, where its up-regulation shortly after osteogenic reprogramming could abolish the bone matrix resorbing function of osteoclasts while its down-regulation during adipogenic transdifferentiation could promote osteoclast function and thus loss of bone mass and concomitant increase of adipose tissue [Justesen et al., 2001; Koo et al., 1998; Meunier et al., 1971; Pei and Tontonoz, 2004; Rosen and Bouxsein, 2006].

SFRP2 was controversially discussed to facilitate or to inhibit osteogenic differentiation depending on the cell culture system [Boland et al., 2004; Oshima et al., 2005]. Our data obtained at the mRNA level support the latter view but this could not be proven by supplementation of culture media with rmSFRP2. While adipogenesis of MSCs was not influenced, the effect of the recombinant protein on osteogenesis could not be determined since cells detached upon addition of rmSFRP2 to the osteogenic differentiation medium. Perhaps the murine recombinant protein could not exactly mimic the effect of its human analogue in the concentration used.

CYR61 is an extracellular matrix-associated signalling protein that is synthesised in various tissues and has been shown to be secreted by osteoblasts but has been mainly related to angiogenesis so far [Lau and Lam, 1999; Lechner et al., 2000; Schütze et al., 2005a; Schütze et al., 2006]. Some recent work using the murine pluripotent mesenchymal stem cell line C3H10T1/2 reported on the up-regulation of CYR61 in response to wingless-type MMTV integration site family member 3A (WNT3A) that has been considered to enhance osteogenic differentiation [Jackson et al., 2005; Si et al., 2006]. Moreover, Si et al. [2006] showed that

silencing of CYR61 expression diminished osteogenesis-specific ALP activity. Although up-regulation of CYR61 was also detected for osteogenic transdifferentiation by our microarray analyses and confirmed by RT-PCR, external addition of rhCYR61 did neither alter osteogenic nor adipogenic differentiation in our cell culture system.

In general, secretion of proteins like CYR61 during transdifferentiation in our cell culture system does not necessarily imply that they function in an autocrine fashion. *In vivo*, secreted proteins may also target neighbouring cells, which in turn respond to this stimulus by signals that influence current differentiation stages. Thus, the effect of a secreted protein on the generation of mature tissues can go beyond differentiation into a single phenotype since it can influence e.g. stimulation of angiogenesis and chemotaxis as reported for CYR61 [Grzeszkiewicz et al., 2002; Lau and Lam, 1999; Schütze et al., 2005a; Schütze et al., 2006]. Interestingly for several of the genes regulated by WNT3A in C3H10T1/2 cells, expression changes were also found in our experiments shortly after initiation of transdifferentiation [Jackson et al., 2005; Si et al., 2006]. Accordingly, regulation patterns in response to WNT3A and after initiation of osteogenic transdifferentiation matched for down-regulation of ANGPTL4, IGF1, and SFRP2 as well as for up-regulation of CYR61, collagen type XI alpha 1 (COL11A1), connective tissue growth factor (CTGF), thrombospondin 1 (THBS1), TNFRSF11B, and WNT1 inducible signalling pathway protein 1 (WISP1). As at the mRNA level neither differential regulation of WNT3A nor of β -catenin was detected during transdifferentiation, their regulation could rather be managed post-transcriptionally at the protein level, e.g. by SFRP2. The down-regulation of SFRP2 in osteogenic and its up-regulation in adipogenic transdifferentiation would meet this assumption, provided that the action of this Wnt antagonist inhibits osteogenesis as reported by Oshima et al. [2005]. Moreover, Wnt signalling could be forwarded via β -catenin-independent mechanisms like the Wnt/G-protein pathway [Kohn and Moon, 2005].

The regulation of several G-protein signalling-associated genes like regulator of G-protein signalling 4 (RGS4) and phospholipase C beta 4 (PLCB4) during transdifferentiation in our cell culture system suggested strong influence of their corresponding proteins on reprogramming either in combination with Wnts or with other factors. Moreover, this indicated the importance of transmembrane signalling during transdifferentiation [Gilman, 1987].

5.3.2 FGF1 as one of the potential key factors of transdifferentiation displays inhibitory effects on adipogenic differentiation as well as on transdifferentiation

The FGF signalling pathway was considered important for initiation of transdifferentiation since several of its members displayed changes in gene expression. Furthermore, FGF1 was reciprocally regulated regarding the different transdifferentiation directions and obtained therefore high bioinformatic scoring amongst the top 50 of the ranking. Regarding its functional mechanism, FGF1 was considered to act in an autocrine fashion that enhanced

osteogenic but inhibited adipogenic transdifferentiation. Accordingly, external addition of rhFGF1 proved its strong inhibitory effect on adipogenic differentiation and transdifferentiation (fig. 27, fig. 28, and fig. 30).

Though FGF1 has contrarily been reported to stimulate adipogenesis in human pre-adipocytes [Hutley et al., 2004], these results could be caused by the proliferative effect of FGF1 on subconfluent pre-adipocytes *in vitro*. Unlike in our experiments where (trans)differentiation experiments were conducted with confluent monolayers, FGF1 could accelerate proliferation in subconfluent condition compared to those not subjected to FGF1 treatment. This would simply promote adipogenesis by earlier achievement of confluence which is a prerequisite for the beginning of adipogenic differentiation [Rosen et al., 2000]. We also showed that proliferation was not stimulated by FGF1 in our cell culture system (fig. 29). Since FGF1 can bind to all four types of FGF receptors [Eswarakumar et al., 2005], differential receptor expression or further factors may be involved that guide signalling possibly via another receptor than in the experiments of Hutley et al. [2004] therefore provoking another outcome. Moreover, foetal rat calvarial cells have been reported to respond differently to FGF1 depending on their maturation stage; while early osteoblasts showed enhanced proliferation, later osteoblasts were retarded in maturation and mineralisation [Tang et al., 1996]. Additionally, systemic administration of FGF1 in ovariectomised, osteoporotic rats has been reported to diminish bone loss and to enhance bone formation [Dunstan et al., 1999]. In our cell culture system, rhFGF1 had no effect on osteogenic differentiation when applied simultaneously with the conventional osteogenic differentiation factors, neither regarding the extent of mineralisation nor the temporal course of the formation of osteogenic markers. Nonetheless, this does not abrogate stimulation of osteogenic transdifferentiation of MSC-derived adipocytes by FGF1 possibly involving other mechanisms than conventional osteogenic differentiation.

The finding and confirmation of the unexpected inhibitory function of FGF1 regarding the adipogenic phenotype served as the “proof of principle” that our approach that includes a new bioinformatic scoring scheme is feasible to detect novel regulators of transdifferentiation and differentiation that decide between osteogenesis and adipogenesis. At the same time, it also emphasises the need for functional analyses. Therefore, the bioinformatic ranking served well as a first filtering method to handle huge data amounts. Subsequent analyses must examine whether changes at the transcription level also affect the protein level and therefore control the initiation of transdifferentiation. Thus, novel molecules might be identified from the results of this screen.

5.4 Perspective

Given the proof of transdifferentiation between the adipogenic and osteogenic lineage in our cell culture system of human MSCs, the age-related fatty degeneration of human bone marrow that is inversely correlated with the loss of bone mass [Beresford et al., 1992; Burkhardt et al., 1987; Gimble et al., 2006; Koo et al., 1998] may at least partly be caused by adipogenic conversion of osteoblasts. The establishment of our cell culture system that employed primary human MSCs to monitor transdifferentiation between the adipogenic and osteogenic lineage set the stage to examine the molecular events provoking the reprogramming of cells. The examination of global gene expression patterns together with the development of a novel bioinformatic scoring scheme paid special attention to genes displaying reciprocal regulation patterns regarding the different transdifferentiation directions and allowed for elucidation of gene products with potentially high functional relevance regarding initiation of the reprogramming processes. The “proof of principle” for our bioinformatic ranking was provided by verification of the inhibitory effect of FGF1 on adipogenic transdifferentiation. Examples for further reasonable and promising approaches to examine the processes underlying transdifferentiation are stated below.

Mechanisms of FGF1 action

Regarding the mechanisms by which FGF1 exerts its inhibitory effect on adipogenic (trans)differentiation, better understanding of the molecular events taking place during adipogenic transdifferentiation would be desirable. It is not clear whether established FGF signalling components are involved or factors not known yet cause the observed effect. Hence, further examinations could elucidate if or which FGF receptor mediates the signal transduction. Moreover, all FGF receptors are receptor tyrosine kinases that can turn on several intracellular signalling pathways like Ras/MAP kinase signalling and phosphoinositol metabolism-mediated cell signalling resulting in modulation of transcription factor activity [Schlessinger, 2000]. Detailed knowledge about the participating pathways could elucidate novel possibilities in order to specifically address molecules *in vivo* that would inhibit the adipogenic conversion.

Effect of FGF1 in animal models

As a first more empirically *in vivo* attempt, application of FGF1 in an osteopenic mouse model that displays accelerated adipogenesis could be examined [Klein et al., 2004]. Possibly treatment with FGF1 could rescue the osteopenic phenotype of these mice by inhibition of adipogenesis. Moreover together with systemically applied FGF2, the interplay between FGF1 inhibiting adipogenesis and FGF2 accelerating osteogenesis could be assessed in ovariectomised, osteoporotic rats or estrogen receptor α knockout mice [Dunstan et al., 1999; Ling et al., 2006; Parikka et al., 2005; Xiao et al., 2002].

Ovariectomised, osteoporotic rats have already been shown to respond to systemic application of FGF1 with decreased bone loss and increased bone formation but changes in adipose tissue were not examined [Dunstan et al., 1999]. FGF2 as enhancer of osteogenesis was only administered locally in the mentioned study but could possibly act in concert with adipogenesis-inhibiting FGF1 when both were applied systemically.

Examination of further highly ranked factors with known or unknown function

Moreover due to the high number of reproducibly and strongly regulated genes, further functional analyses should be performed. Since our approach proved already functional relevance of a key factor, not only members of known signalling pathways but also hypothetical genes and genes without known function are expected to affect the initiation of transdifferentiation. Methods of choice for functional analyses will thereby depend on the available information regarding the characteristics of each protein that should be addressed. Whereas the influence of some highly ranked secreted proteins was tested *in vitro* in the course of this doctorate by addition of the recombinant proteins to the cell culture media, intracellular proteins could be examined by gene silencing assays using short interference (si)RNAs. Hypothetical genes and such with unknown localisation could be approached by establishment of their over-expression in MSCs. For both, gene silencing and overexpression, lentiviral systems would be suitable since they allow for stable expression of siRNAs and transgenes, respectively [Christian et al., 2005; Saunders et al., 2006].

Therapeutic potential of gene products regulated during transdifferentiation

Altogether, our results emphasise the importance of regulatory mechanisms that balance between the adipogenic and osteogenic lineage and give insight into gene expression changes shortly after initiation of reprogramming. Besides the considerations regarding transdifferentiation, our microarray data may also provide further knowledge about the transcriptome of differentiated cells. When compared to the transcriptome of undifferentiated MSCs, novel factors of relevance for induction and maintenance of the osteogenic versus adipogenic differentiation pathway could be identified. Moreover, since FGF1 acts as a potent inhibitor of adipogenic transdifferentiation and further functional assays are likely to provide more proteins involved in lineage determination, knowledge about the influence of these factors could help to find potential targets for therapeutic interventions that inhibit adipogenic degeneration and simultaneously facilitate osteogenesis *in vivo*, especially with ageing.

7 Appendix

7.1 Fold changes of gene regulation after initiation of adipogenic transdifferentiation – GeneChips HG-U 133A

Tab. 12 Fold changes of gene regulation 3 h after initiation of adipogenic transdifferentiation

Gene name	Gene symbol	Affymetrix probe set ID	Fold change + 3 h
ADP-ribosylation factor-like 7	ARL7	202208_s_at	3.2
ADP-ribosylation factor-like 7	ARL7	202207_at	2.5
adrenomedullin	ADM	202912_at	-2.8
amphiregulin (schwannoma-derived growth factor)	AREG	205239_at	3.6
ankyrin repeat and SOCS box-containing 1	ASB1	212819_at	-2.9
apolipoprotein L domain containing 1	APOLD1	221031_s_at	4.5
ATPase, Ca ⁺⁺ transporting, plasma membrane 1	ATP2B1	212930_at	-10.4
ATP-binding cassette, sub-family A (ABC1), member 5	ABCA5	213353_at	-3.9
cAMP responsive element modulator	CREM	209967_s_at	8.3
cAMP responsive element modulator	CREM	207630_s_at	3.6
cathepsin Z	CTSZ	210042_s_at	5.2
cathepsin Z	CTSZ	212562_s_at	5.2
Cbp/p300-interacting transactivator, with Glu/Asp-rich carboxy-terminal domain, 2	CITED2	209357_at	-2.8
chemokine (C-X3-C motif) ligand 1	CX3CL1	823_at	-3.3
chemokine (C-X3-C motif) ligand 1	CX3CL1	203687_at	-10.7
chromobox homolog 4 (Pc class homolog, Drosophila)	CBX4	206724_at	2.9
chromosome 6 open reading frame 56	C6orf56	204049_s_at	-2.5
cofactor required for Sp1 transcriptional activation, subunit 9, 33kDa	CRSP9	204349_at	-12.0
colon carcinoma related protein	LOC51159	220327_at	-2.5
core-binding factor, runt domain, alpha subunit 2; translocated to, 1; cyclin D-related	CBFA2T1	205528_s_at	-16.1
cystathionase (cystathionine gamma-lyase)	CTH	217127_at	3.8
cystathionase (cystathionine gamma-lyase)	CTH	206085_s_at	2.6
cysteine knot superfamily 1, BMP antagonist 1	CKTSF1B1	218469_at	-2.5
cysteine knot superfamily 1, BMP antagonist 1	CKTSF1B1	218468_s_at	-2.5
cysteine-rich, angiogenic inducer, 61	CYR61	210764_s_at	-4.1
cysteine-rich, angiogenic inducer, 61	CYR61	201289_at	-5.2
dapper homolog 1, antagonist of beta-catenin (xenopus)	DACT1	219179_at	-2.8
decidual protein induced by progesterone	DEPP	209182_s_at	-3.1
distal-less homeo box 2	DLX2	207147_at	2.8
DnaJ (Hsp40) homolog, subfamily B, member 4	DNAJB4	203810_at	-2.5
DnaJ (Hsp40) homolog, subfamily B, member 4	DNAJB4	203811_s_at	-2.7
downregulated in ovarian cancer 1	DOC1	204135_at	-4.1
dual specificity phosphatase 4	DUSP4	204014_at	3.9
dual specificity phosphatase 6	DUSP6	208891_at	-4.0
dual specificity phosphatase 6	DUSP6	208892_s_at	-4.8
dual specificity phosphatase 7	DUSP7	214793_at	-3.1
dual-specificity tyrosine-(Y)-phosphorylation regulated kinase 1A	DYRK1A	211541_s_at	3.9
early growth response 2 (Krox-20 homolog, Drosophila)	EGR2	205249_at	-3.8
early growth response 3	EGR3	206115_at	-3.4
ectodermal-neural cortex (with BTB-like domain)	ENC1	201341_at	-2.7
GATA binding protein 6	GATA6	210002_at	-2.5
guanine nucleotide binding protein (G protein), alpha activating activity polypeptide, olfactory type	GNAL	218177_at	4.9
guanine nucleotide binding protein (G protein), alpha activating activity polypeptide, olfactory type	GNAL	218178_s_at	4.1
heme oxygenase (decycling) 1	HMOX1	203665_at	-2.5
HIF-1 responsive RTP801	RTP801	202887_s_at	3.2
high mobility group AT-hook 2	HMGA2	208025_s_at	-3.2
homeo box A1	HOXA1	214639_s_at	3.0
human immunodeficiency virus type 1 enhancer binding protein 1	HIVEP1	204512_at	-2.7
hyaluronan synthase 1	HAS1	207316_at	3.8
hypothetical protein FLJ22341	FLJ22341	219202_at	7.3
inhibitor of DNA binding 2, dominant negative helix-loop-helix protein	ID2	201566_x_at	2.8
inhibitor of DNA binding 4, dominant negative helix-loop-helix protein	ID4	209293_x_at	4.9
inhibitor of DNA binding 4, dominant negative helix-loop-helix protein	ID4	209292_at	4.7
inhibitor of DNA binding 4, dominant negative helix-loop-helix protein	ID4	209291_at	3.6
intercellular adhesion molecule 1 (CD54), human rhinovirus receptor	ICAM1	202638_s_at	-2.8
intersectin 2	ITSN2	209898_x_at	-10.3
KIAA0701 protein	KIAA0701	213118_at	-6.6
KIAA0874 protein	KIAA0874	216563_at	-2.7
Kruppel-like factor 4 (gut)	KLF4	220266_s_at	2.8
Kruppel-like factor 5 (intestinal)	KLF5	209212_s_at	-2.9
Kruppel-like factor 7 (ubiquitous)	KLF7	204334_at	-3.0
leukemia inhibitory factor (cholinergic differentiation factor)	LIF	205266_at	-2.9

Gene name	Gene symbol	Affymetrix probe set ID	Fold change + 3 h
LIM protein (similar to rat protein kinase C-binding enigma)	LIM	221994_at	-2.9
matrix metalloproteinase 1 (interstitial collagenase)	MMP1	204475_at	-2.9
myosin VI	MYO6	210480_s_at	-2.6
myosin VI	MYO6	203215_s_at	-3.0
neural precursor cell expressed, developmentally down-regulated 9	NEDD9	202150_s_at	-2.6
nuclear factor of activated T-cells, cytoplasmic, calcineurin-dependent 1	NFATC1	211105_s_at	2.6
nuclear receptor subfamily 4, group A, member 1	NR4A1	202340_x_at	2.6
nuclear receptor subfamily 4, group A, member 2	NR4A2	204621_s_at	9.6
nuclear receptor subfamily 4, group A, member 2	NR4A2	216248_s_at	9.5
nuclear receptor subfamily 4, group A, member 2	NR4A2	204622_x_at	7.4
nuclear receptor subfamily 4, group A, member 3	NR4A3	209959_at	2.7
nuclear receptor subfamily 4, group A, member 3	NR4A3	207978_s_at	2.5
peptidylprolyl isomerase F (cyclophilin F)	PPIF	201490_s_at	2.6
period homolog 1 (Drosophila)	PER1	202861_at	2.9
phosphodiesterase 4B, cAMP-specific (phosphodiesterase E4 dunce homolog, Drosophila)	PDE4B	203708_at	5.5
phosphodiesterase 4D, cAMP-specific (phosphodiesterase E3 dunce homolog, Drosophila)	PDE4D	204491_at	4.6
phosphodiesterase 4D, cAMP-specific (phosphodiesterase E3 dunce homolog, Drosophila)	PDE4D	210836_x_at	3.0
phosphodiesterase 4D, cAMP-specific (phosphodiesterase E3 dunce homolog, Drosophila)	PDE4D	210837_s_at	2.7
phospholamban	PLN	204939_s_at	-2.9
pim-1 oncogene	PIM1	209193_at	-3.3
potassium voltage-gated channel, Isk-related family, member 4	KCNE4	222379_at	5.9
prostaglandin E receptor 4 (subtype EP4)	PTGER4	204897_at	-4.0
protein kinase C-like 2	PRKCL2	212628_at	-2.6
protein phosphatase 1, regulatory (inhibitor) subunit 3C	PPP1R3C	204284_at	3.2
RAB20, member RAS oncogene family	RAB20	219622_at	2.6
regulator of G-protein signalling 16	RGS16	209324_s_at	-5.7
regulator of G-protein signalling 16	RGS16	209325_s_at	-5.7
regulator of G-protein signalling 2, 24kDa	RGS2	202388_at	6.1
retinoic acid induced 3	RAI3	212444_at	2.9
SAM domain, SH3 domain and nuclear localisation signals, 1	SAMSN1	220330_s_at	-4.1
serine/threonine kinase 38 like	STK38L	212572_at	-3.5
serine/threonine kinase 38 like	STK38L	212565_at	-3.8
signal sequence receptor, gamma (translocon-associated protein gamma)	SSR3	217790_s_at	2.8
solute carrier family 2 (facilitated glucose transporter), member 3	SLC2A3	202499_s_at	4.7
solute carrier family 2 (facilitated glucose transporter), member 14	SLC2A14	222088_s_at	3.8
solute carrier family 2 (facilitated glucose transporter), member 3	SLC2A3	202498_s_at	3.5
solute carrier family 2 (facilitated glucose transporter), member 14	SLC2A14	216236_s_at	2.9
solute carrier family 2 (facilitated glucose transporter), member 3	SLC2A3	202497_x_at	2.9
solute carrier family 7 (cationic amino acid transporter, y+ system), member 5	SLC7A5	201195_s_at	2.9
sprouty homolog 2 (Drosophila)	SPRY2	204011_at	-2.5
superoxide dismutase 2, mitochondrial	SOD2	215078_at	-3.8
thioredoxin interacting protein	TXNIP	201008_s_at	-2.6
TNF receptor-associated factor 1	TRAF1	205599_at	-2.9
TNF-induced protein	GG2-1	210260_s_at	-2.5
TNF-induced protein	GG2-1	208296_x_at	-3.6
topoisomerase (DNA) II alpha 170kDa	TOP2A	201291_s_at	-2.9
transcription factor 8 (represses interleukin 2 expression)	TCF8	208078_s_at	5.9
translation initiation factor IF2	IF2	201027_s_at	-6.1
tumor rejection antigen (gp96) 1	TRA1	216449_x_at	-2.7
vasopressin-induced transcript	VIP32	218631_at	2.6
zinc finger protein 217	ZNF217	203739_at	-3.6
zinc finger protein 331	ZNF331	219228_at	7.6

Fold change + 3 h = differential gene expression 3 h after initiation of transdifferentiation.

Tab. 13 Fold changes of gene regulation 24 h after initiation of adipogenic transdifferentiation

Gene name	Gene symbol	Affymetrix probe set ID	Fold change + 24 h
3-hydroxysteroid epimerase	RODH	205700_at	-3.4
acetyl-Coenzyme A carboxylase beta	ACACB	43427_at	3.0
acetyl-Coenzyme A carboxylase beta	ACACB	49452_at	3.0
adenosine deaminase	ADA	204639_at	2.6

Transdifferentiated samples were compared to differentiated controls. Fold changes for transcripts with reproducible regulation directions regarding two different MSC charges (array 1 and array 2) are listed by gene name. + 3 h = 3 h after initiation of adipogenic transdifferentiation.

Tab. 15 Fold changes of gene expression 24 h after initiation of adipogenic transdifferentiation

Gene title	Gene symbol	Affymetrix probe set ID	+ 24 h sample_array 1 versus control_array 1 [fold change]	+ 24 h sample_array 2 versus control_array 2 [fold change]

Reliably measured and 3 h after initiation of adipogenic transdifferentiation differentially regulated probe sets with at least one P detection call in the compared samples for each experimental set were subjected to GStat analyses. The total number of regulated and not regulated probe sets detected on the GeneChip served as reference and is given in the respective column. Only over-represented GO classes containing at least 5 genes and a GStat p-value ≤ 0.1 were considered. Adipogenic transdifferentiation exhibited 159 differentially regulated target probe sets that were analyzed in reference to all 20,357 reliably measured probe sets for the 3 h time point. The GO class of cellular component did not show any relevant over-representation 3 h after initiation of adipogenic transdifferentiation under the criteria stated above. Gene symbols are stated according to the HUGO gene nomenclature.

Tab. 19 GStat analysis – 24 h after initiation of adipogenic transdifferentiation

GOstat analysis results for genes showing differential regulation 24 h after initiation of adipogenic transdifferentiation are depicted under the same prerequisites as described for tab. 18. Altogether, 418 target probe sets were referred to 21,892 reliably measured probe sets for the 24 h time point.

Tab. 20 GOstat analysis 3 h after initiation of osteogenic transdifferentiation

GOstat analysis results for genes showing differential regulation 3 h after initiation of osteogenic transdifferentiation are depicted under the same prerequisites as described for tab. 18. Altogether, 92 target probe sets were obtained 3 h after initiation of transdifferentiation and analysed to the reference of all 22,634 reliably measured probe sets at this time point.

GOstat analysis results for genes showing differential regulation 24 h after initiation of osteogenic transdifferentiation are depicted under the same prerequisites as described for tab. 18. Altogether, 1,196 target probe sets were found and analysed to the reference of all 24,108 reliably measured probe sets 24 h after initiation of transdifferentiation.

7.4 Abbreviations

°C	degree Celsius
µg	microgram(s)
µm	micrometre(s)
µM	micromolar = micromol per litre
1D	one dimensional
ALP	alkaline phosphatase
APS	ammonium persulfate
bp	base pair
cDNA	complementary deoxyribonucleic acid
CHAPS	(3-[(3-Cholamidopropyl)-dimethylammonio]-propane-sulfonate)
CO ₂	carbon dioxide
cRNA	complementary ribonucleic acid
d	day(s)
ddNTPs	dideoxynucleotide triphosphates
DMEM	Dulbecco's modified eagle's medium
DMSO	dimethylsulfoxide
DNA	deoxyribonucleic acid
dNTPs	deoxynucleotide triphosphates
DTT	dithiothreitol
E	extinction unit
EDTA	ethylenediaminetetraacetic acid
FBS	foetal bovine serum
FGF1	fibroblast growth factor 1
fig.	figure
h	hour(s)
HCl	hydrochloric acid
HPLC	high performance liquid chromatography
IBMX	3-isobutyl-1-methylxanthine
IGF1	insulin-like growth factor 1
l	litre
mA	milliampere
min	minute(s)
ml	microlitre(s)
mM	millimolar = millimol per litre
M-MLV	moloney murine leukemia virus
mRNA	messenger RNA
MSC	mesenchymal stem cell
nM	nanomolar = nanomol per litre
PBS	phosphate buffered saline
rhCYR61	recombinant human cysteine-rich angiogenic inducer 61
rhFGF acidic	recombinant human fibroblast growth factor, acidic
rhIGF-I	recombinant human insulin like growth factor I
rhOPG/TNFRSF11B	recombinant human osteoprotegerin/tumor necrosis factor receptor superfamily, member 11b
rmsFRP2	mouse recombinant secreted frizzled-related protein 2
RNA	ribonucleic acid
rpm	rounds per minute
RT	reverse transcriptase
RT-PCR	reverse transcriptase polymerase chain reaction
SDS	sodium dodecyl sulfate
SDS-PAGE	sodium dodecyl sulfate polyacrylamide gel electrophoresis

SFRP2	secreted frizzled-related protein 2
tab.	table
<i>Taq</i>	<i>Thermus aquaticus</i>
TEMED	N,N,N',N'-tetramethyl ethylenediamine
TNFRSF11B	tumor necrosis factor receptor superfamily, member 11b (osteoprotegerin)
Tris base	tris(hydroxymethyl)aminomethane
U	unit(s)
UV	ultraviolet
v/v	volume per volume
w/v	weight per volume
x	times, -fold

7.5 Curriculum Vitae

Personal information

Surname and first names: **Schilling, Maria Tatjana**
Date of birth: 5 February 1979
Place of birth: San Miguel de Tucuman, Argentina
Address: St.-Nepomuk-Str. 6, D-97218 Gerbrunn, Germany
Status: unmarried
Nationality: German

Education and training

1985 - 1989 Elementary school, Baunach
1989 - 1998 Grammar school "Gymnasium der Englischen Fräulein", Bamberg
June 1998 General qualification for university entrance („Abitur“)
1998 - 2003 Studies of biology at the Julius Maximilians University Würzburg,
Main subjects: biotechnology, cellular and developmental biology, and
microbiology
Diploma thesis at the Chair of Biotechnology: "Cryoprotection of Cells"
December 2003 Diploma certificate as biologist
2004 - 2007 PhD thesis at the Julius Maximilians University Würzburg,
Orthopedic Clinic, Orthopedic Center for Musculoskeletal Research,
Molecular Orthopedics and Cell Biology,
supervised by PD Dr. Norbert Schütze and Prof. Dr. Franz Jakob

Scholarships and awards

March 2007 „Von Recklinghausen“ award of the "Deutsche Gesellschaft für Endokrinologie" (German Society of Endocrinology) for the manuscript "Plasticity in Adipogenesis and Osteogenesis of Human Mesenchymal Stem Cells" (see 7.6)
March 2006 Scholarship of the "Deutsche Akademie der osteologischen und rheumatologischen Wissenschaften" (German Academy of Osteologic and Rheumatologic Sciences) to attend the Young Investigator Osteology Symposium 2006 (YIOSS'2006) within the Osteology 2006 conference in Köln, Germany
September 2005 Conference scholarship of the „Deutsche Akademie der osteologischen und rheumatologischen Wissenschaften“ to attend the 5th Baltic Bone and Cartilage Conference 2005 in Naantali, Finland

October 2004 Poster award: best poster of the session at the 90th annual conference of the “Deutsche Gesellschaft für Orthopädie und Orthopädische Chirurgie“ (German Society for Orthopaedics and Orthopaedic Surgery) 2004 in Berlin, Germany; title: “Plasticity between Adipogenic and Osteogenic Differentiation in Human Mesenchymal Stem Cells of the Bone Marrow”

7.7 Acknowledgement

This work was performed at the Orthopedic Center for Musculoskeletal Research (Faculty of Medicine, University of Würzburg) residing in the Orthopedic Clinic which is managed by the District of Lower Franconia (Bezirk Unterfranken). Therefore, I like to thank all colleagues of the Research Center as well as all people of the clinic staff who contributed somehow or other to this work.

I like to express my special gratitude to my supervisors PD Dr. Norbert Schütze and Prof. Dr. Franz Jakob who warmly welcomed and introduced me into a fascinating project. I am thankful for promoting this doctorate with their scientific expertise and helpful discussions as well as for their continuing support of my academical development. Moreover, I appreciate the many opportunities to present and discuss this work at national and international symposia from which I benefited a lot.

I am thankful to Prof. Dr. Georg Krohne of the Faculty of Biology (University of Würzburg) for accepting the position of an assessor, thereby enabling this scientific doctorate at the Faculty of Medicine.

I am very grateful to Prof. Dr. Jochen Eulert, the head of the Orthopedic Clinic, who appreciates and supports basic research at his clinic, thus providing an excellent interdisciplinary academic environment.

I am grateful to Jutta Schneidereit for the performance of preliminary work contributing to the approval of this project by the German Research Foundation (Deutsche Forschungsgemeinschaft).

I am thankful to PD Dr. Ludger Klein-Hitpass who helped me a lot with understanding and interpreting microarrays.

I appreciate the cooperation with Prof. Dr. Ralf Zimmer and Dr. Robert Küffner of the Institute of Informatics at the Ludwig Maximilians University in Munich who helped with the bioinformatic evaluation of our data.

I am very grateful to Susanne Jatzke and Manuela Kunz for their help and patience especially at the beginning of my doctorate when they made me familiar with various molecular methods.

I am thankful to all people, most of all to Viola Monz, who helped me with my laboratory tasks when I was attending symposia or busy with writing.

Furthermore, I like to thank Dr. Regina Ebert, Meike Weber, Rita Wagemanns, Andrea Heymer, Dr. Lothar Seefried, and Dr. Akif Ince who shared an office space with me for working group-independent, encouraging scientific and non-scientific discussions. Thereby, special thanks go to Regina for helping to eliminate the typing errors of this manuscript.

I am grateful to Dr. Ulrich Nöth and Martina Regensburger of the Tissue Engineering group at the Orthopedic Center of Musculoskeletal Research for providing and isolating the primary MSCs.

I am thankful to all trainees and medical students, especially to Ulrike Meyer and Christian Kilgenstein, for their interest in research.

I like to thank Monika Hofmann for her help with any kind of organisational tasks in the Orthopedic Clinic.

I like to thank Mr. Kemmer and his team of the technical service of the Orthopedic Clinic for their prompt help and for sorting out rather unconventional tasks facilitating our work in the laboratory.

I like to thank my boyfriend Christian very much for his support, understanding and encouragement during all stages of this doctorate, especially in the last few weeks.

Finally, I am particularly grateful to my parents for their unquestioning support during the whole course of my studies.

This work was funded by the German Research Foundation and the District of Lower Franconia.
