

Tafel XVII-1-1

Der exakte 2^3 -Felder-Kontingenztest. (BROWN-HEINZE-KRÜGER-Tafeln)

Aus der Originalarbeit der später verkürzt eingereichten Arbeit von BROWN, C. C., B. HEINZE und H. P. KRÜGER: Tafeln eines exakten 2^3 -Felder-Kontingenztests. EDV in Biologie und Medizin, 1975 (im Druck), mit freundlicher Genehmigung der Verfasser und des Herausgebers.

Die Tafel enthält die exakten Überschreitungswahrscheinlichkeiten P unter H_0 , wonach ein Zeilenmerkmal A mit $k = 2$ Klassen, ein Spalten-Mm B mit $m = 2$ Klassen und ein Schichten-Mm C mit $s = 2$ Klassen allseitig unabhängig sind. Als Parameter abzulesen sind (1) der Stichprobenumfang N der dreidimensionalen Kontingenztafel (Kontingenzwürfel), (2) die Häufigkeit (Zeilensumme $n_{1..} \geq N/2$, mit der die häufigere (positive) Variante des Zeilen-Mms vertreten ist), (3) die Häufigkeit (Spaltensumme) $n_{.1.} \geq N/2$, mit der die häufigere (positive) Variante des Spalten-Mms vertreten ist (4) die Häufigkeit (Schichtensumme) $n_{..1} \geq N/2$, mit der die häufigere (positive) Variante des Schichten-Mms vertreten ist, (5) die Häufigkeit n_{111} (Besetzungszahl des oberen linken hinteren Oktanten), mit der alle drei Mm in positiver Ausprägung auftreten, (6) die Häufigkeit n_{122} (Besetzungszahl des oberen rechten vorderen Oktanten), mit der das Zeilen-Mm in positiver und die beiden übrigen Mm in negativer Ausprägung auftreten, (7) die Häufigkeit n_{212} (Besetzungszahl des unteren linken vorderen Oktanten), mit der das Spalten-Mm in positiver und die übrigen beiden Mm in negativer Ausprägung auftreten, und (8) die Häufigkeit n_{221} (Besetzungszahl des unteren rechten hinteren Oktanten), mit der das Schichten-Mm in positiver und die übrigen Mm in negativer Ausprägung auftreten. Die drei Alternativ-Mm müssen dabei bezüglich ihrer Ausprägung so bezeichnet werden, daß die häufigere der beiden Ausprägungen als die Positiv-Ausprägung definiert ist. Die Tafel gilt für Werte $N = 5(1)15$.

Ablesebeispiel: Der folgende Kontingenzwürfel mit dem Stichprobenumfang von $N = 12$ hat die angegebenen Besetzungszahlen n_{ijk} und die daraus zu berechnenden Randsummen der Positiv-Ausprägungen der Alternativ-Mm A , B und C : $n_{1..} = 5 + 1 + 1 + 0 = 7$, $n_{.1.} = 5 + 1 + 1 + 0 = 7$ und $n_{..1} = 5 + 1 + 1 + 0 = 7$. Wäre eine Positiv-Ausprägungsrandsomme kleiner als $6 = 12/2$, müßte das entsprechende Merkmal umgepolt werden.

Wir sehen, daß offenbar der obere linke hintere Oktant mit 5 und der untere rechte vordere mit 3 überfrequentiert sind, während alle übrigen 6 Oktanten einschließlich des nicht sichtbaren mit $n_{211} = 0$ unterfrequentiert sind. Da die 2 Felder der Raumdiagonalen überfrequentiert sind, besteht eine Gesamtkontingenz, die sich auch in Kontingenzen zwischen

je 2 Mm (Double-Kn) niederschlägt. Wären 2 Oktanten über- und 3 unterfrequentiert, so bestünde ebenfalls eine Gesamtkontingenz, die sich aber nicht in Double-Kn niederschlagen würde. Zur Signifikanzbeurteilung suchen wir das Parameter-Oktupel.

N	$n_{1..}$	$n_{.1.}$	$n_{..1}$	n_{111}	n_{122}	n_{212}	n_{221}	P
12	7	7	7	5	0	1	1	0,0231

in der Tafel auf und lesen in der letzten Spalte dazu ein $P = 0,0231$ ab. P ist die Wahrscheinlichkeit, daß die obige oder eine extremere 8-Felder-Verteilung bei Unabhängigkeit der 3 Mm zustande kommt; als extremer gelten dabei alle Verteilungen, deren Punktwahrscheinlichkeit höchstens so groß ist wie die Punktwahrscheinlichkeit der beobachteten Verteilung.
